# Blocks – Alphabetical List

---

controlengineers.ir

# Abs

Output absolute value of input

## Library

Math Operations

## Description

The Abs block outputs the absolute value of the input.

For signed-integer data types, the absolute value of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block:

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> <li>For 8-bit signed integers, -128 maps to 127.</li> <li>For 16-bit signed integers, -32768 maps to 32767.</li> <li>For 32-bit signed integers, -2147483648 maps to 2147483647.</li> </ul>
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> <li>For 8-bit signed integers, -128 remains -128.</li> <li>For 16-bit signed integers, -32768 remains -32768.</li> <li>For 32-bit signed integers, -2147483648 remains -2147483648.</li> </ul>

The Abs block supports zero-crossing detection. However, when you select **Enable zero-crossing detection** on the dialog box, the block does not report the simulation minimum

or maximum in the Fixed-Point Tool. If you want to use the Fixed-Point Tool to analyze a model, disable zero-crossing detection for all Abs blocks in the model first.

## Data Type Support

The Abs block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

The block also accepts complex floating-point inputs. For more information, see “Data Types Supported by Simulink” in the Simulink® documentation.

## Parameters

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as

SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in Simulink User's Guide for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer™ documentation.

### Saturate on integer overflow

Action	Reason for Taking This Action	What Happens	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to the maximum value that the data type can represent.	The number 130 does not fit in a signed 8-bit integer and saturates to 127.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

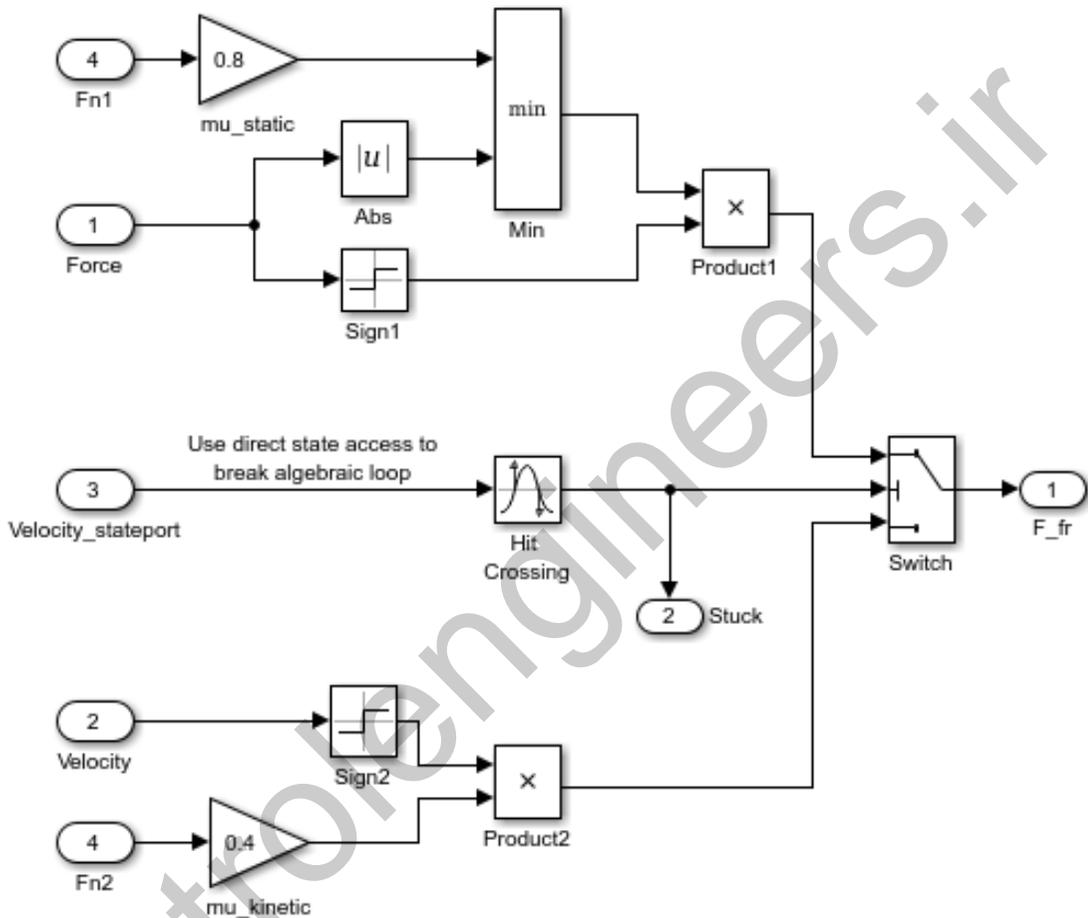

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Examples

### Usage as an Input to a MinMax Block

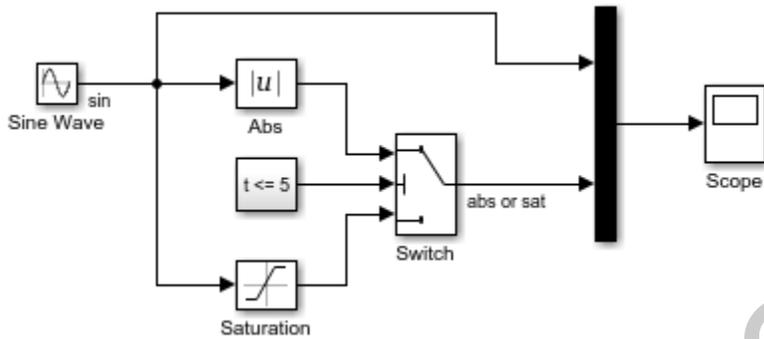

The `sldemo_hardstop` model shows how you can use the `Abs` block as an input to the `MinMax` block.

In the `sldemo_hardstop` model, the `Abs` block is in the `Friction Model` subsystem.

### Usage as an Input to a Switch Block

The `sldemo_zerxing` model shows how you can use the `Abs` block as an input to the `Switch` block.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

## Action Port

Implement Action subsystems used in `if` and `switch` control flow statements

## Library

Ports & Subsystems

## Description

Action Port blocks implement action subsystems used in `if` and `switch` control flow statements. The `If Action Subsystem` and the `Switch Case Action Subsystem` blocks each contain an Action Port block.

## Data Type Support

Action Port blocks do not have data inputs or outputs.

## Parameters

- “States when execution is resumed” on page 1-8
- “Propagate sizes of variable-size signals” on page 1-11

## States when execution is resumed

Specify how to handle internal states when a subsystem with an Action Port block reenables.

### Settings

**Default:** held

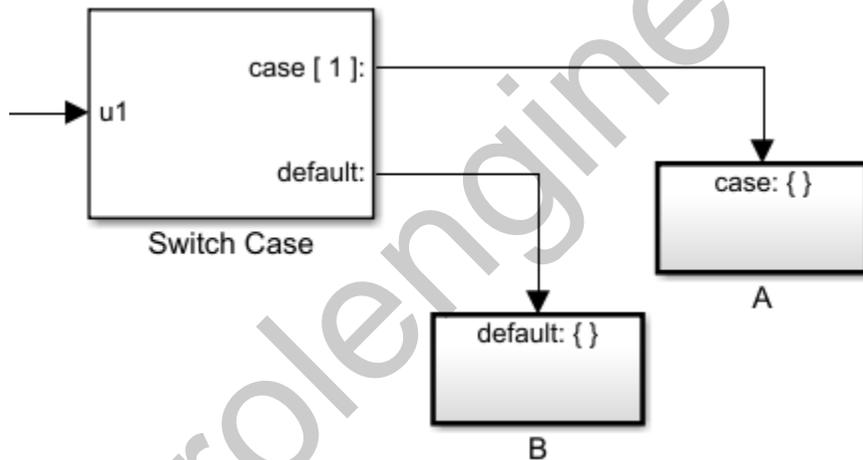

held

When the subsystem reenables, retains the states of the Action subsystem with their previous values. Retains the previous values of states between calls even if calling other member Action subsystems of an if -else or switch control flow statement.

### reset

Reinitializes the states of the Action subsystem to initial values when the subsystem reenables.

Reenablement of a subsystem occurs when called and the condition of the call is true after having been previously false. In the following example, the Action Port blocks for both Action subsystems A and B have the **States when execution is resumed** parameter set to reset.

If case[1] is true, call Action subsystem A. This result implies that the default condition is false. When later calling B for the default condition, its states are reset. In the same way, Action subsystem A states are reset when calling A right after calling Action subsystem B.

Repeated calls to the Action subsystem of a case does not reset its states. If calling A again right after a previous call to A, this action does not reset the states of A. This behavior is because the condition of case[1] was not previously false. The same applies to B.

### Command-Line Information

Parameter: InitializeStates

**Type:** character vector  
**Value:** 'held' | 'reset' |  
**Default:** 'held'

controlengineers.ir

## Propagate sizes of variable-size signals

Specify when to propagate a variable-size signal.

### Settings

**Default:** Only when execution is resumed

Only when execution is resumed

Propagates variable-size signals only when reenabling the subsystem containing the Action Port block.

During execution

Propagates variable-size signals at each time step.

### Command-Line Information

**Parameter:** PropagateVarSize

**Type:** character vector

**Value:** 'Only when execution is resumed' | 'During execution'

**Default:** 'Only when execution is resumed'

## Characteristics

Sample Time	Inherited from driving If or Switch Case block
-------------	--

If, If Action Subsystem, Switch Case, Switch Case Action Subsystem

**Introduced before R2006a**

# Algebraic Constraint

Constrain input signal to zero

## Library

Math Operations

## Description

The Algebraic Constraint block constrains the input signal  $f(z)$  to zero and outputs an algebraic state  $z$ . The block outputs the value that produces a zero at the input. The output must affect the input through a direct feedback path, that is, the feedback path contains only blocks with direct feedthrough. For example, you can specify algebraic equations for index 1 differential-algebraic systems (DAEs).

## Algorithm

The Algebraic Constraint block uses a dogleg trust-region algorithm to solve algebraic loops [1], [2].

## Data Type Support

The Algebraic Constraint block accepts and outputs real values of type `double`.

## Parameters

Initial guess

An initial guess for the solution value. The default is 0.

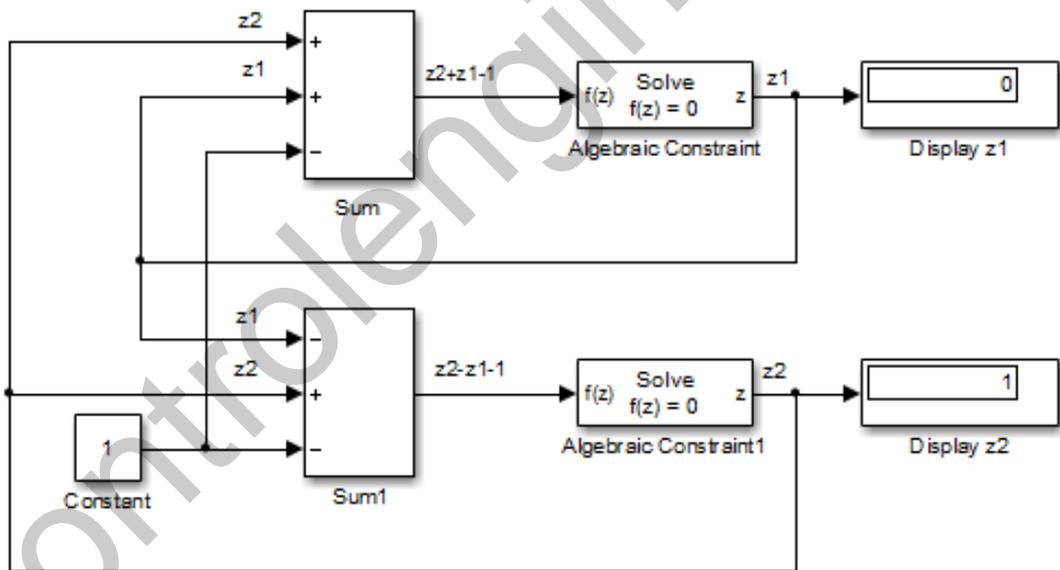

## Example

By default, the **Initial guess** parameter is zero. You can improve the efficiency of the algebraic-loop solver by providing an **Initial guess** for the algebraic state  $z$  that is close to the solution value.

For example, the following model solves these equations:

$$\begin{aligned} z_2 + z_1 &= 1 \\ z_2 - z_1 &= 1 \end{aligned}$$

The solution is  $z_2 = 1, z_1 = 0$ , as the Display blocks show.

## Characteristics

Data Types	Double
------------	--------

Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	No

## Argument Inport

Argument input port for Simulink Function block

### Description

This block is an input argument port for a function that you define in the Simulink Function block.

### Data Type Support

The Argument Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Argument Inport block also accepts a bus object as a data type.

The numeric and data types of the block output are the same as those of its input. You can specify the signal type and data type of an input argument to an Argument Inport block using the **Signal type** and **Data type** parameters. For more information, see “Data Types Supported by Simulink”.

### Parameters

- “Port number” on page 1-17
- “Argument Name” on page 1-17
- “Minimum” on page 1-18
- “Maximum” on page 1-19
- “Data type” on page 1-20

- “Show data type assistant” on page 1-22
- “Mode” on page 1-23
- “Data type override” on page 1-25
- “Signedness” on page 1-26
- “Word length” on page 1-27
- “Scaling” on page 1-28
- “Fraction length” on page 1-29
- “Slope” on page 1-30
- “Bias” on page 1-30
- “Output as nonvirtual bus” on page 1-31
- “Lock data type settings against changes by the fixed-point tools” on page 1-32
- “Port dimensions” on page 1-32
- “Signal type” on page 1-33

## Port number

Specify the port number of the block.

### Settings

**Default: 1**

This parameter controls the order in which the port that corresponds to the block appears in the parent subsystem or model block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Argument Name

### Settings

**Default: u**

This parameter provides the name of the input argument in the function prototype of the Simulink Function block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Minimum

Specify the minimum value for the block to output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value for the block to output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see Simulink.BusElement.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Data type

Specify the output data type of the argument input.

### Settings

**Default:** double

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Data type is enumerated, for example, Enum: Basic Colors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Built in

**Built in**

Built-in data types. Selecting **Built in** enables a second text box to the right. Select one of the following:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

**Fixed point**

Fixed-point data types.

**Enumerated**

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

**Bus object**

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

**Expression**

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

### **Dependency**

Clicking the **Show data type assistant** button enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

For more information, see “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow® chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Output as nonvirtual bus

Output a nonvirtual bus.

### Settings

**Default:** Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

### Tips

- Select this option if you want code generated from this model to use a C structure to define the structure of the bus signal output by this block.
- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. Therefore, if you select this option all signals in the bus must have the same sample time. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Lock data type settings against changes by the fixed-point tools

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Port dimensions

Specify the dimensions of the input signal to the block.

### Settings

**Default:** 1

Valid values are:

n	Vector signal of width n accepted
[m n]	Matrix signal having m rows and n columns accepted

## Signal type

Specify the numeric type of the argument input.

### Settings

**Default:** real

real

Specify the numeric type as a real number.

complex

Specify the numeric type as a complex number.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Dimensionalized	Yes
Multidimensionalized	Yes
Zero-Crossing Detection	No

## See Also

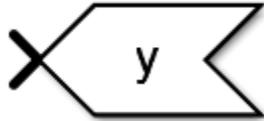

Argument Outport

Simulink Function

**Introduced in R2014b**

## Argument Output

Argument output port for Simulink Function block

### Description

This block is an output argument port for a function that you define in the Simulink Function block.

### Data Type Support

The Argument Output block accepts real or complex signals of any data type that Simulink supports. An Argument Output block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as those of its input. The Argument Output block also accepts a bus object as a data type.

For more information, see “Data Types Supported by Simulink”.

### Parameters

- “Port number” on page 1-35
- “Argument Name” on page 1-35
- “Minimum” on page 1-37
- “Maximum” on page 1-38
- “Data type” on page 1-38
- “Show data type assistant” on page 1-40

- “Mode” on page 1-40
- “Data type override” on page 1-41
- “Signedness” on page 1-43
- “Word length” on page 1-43
- “Scaling” on page 1-44
- “Fraction length” on page 1-44
- “Slope” on page 1-45
- “Bias” on page 1-46
- “Lock output data type setting against changes by the fixed-point tools” on page 1-46
- “Output as nonvirtual bus” on page 1-47
- “Port dimensions” on page 1-47
- “Signal type” on page 1-48

## Port number

Specify the port number of the block.

### Settings

**Default:** 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Argument Name

### Settings

Specify the name of the output argument.

**Default:** y

This parameter provides the name of the output argument in the function prototype of the Simulink Function block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Minimum

Specify the minimum value for the block to output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value for the block to output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Data type

Specify the output data type of the external input.

### Settings

**Default:** double

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Data type is enumerated, for example, Enum: BasicColors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example Simulink.NumericType

Do not specify a bus object as the expression.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

### Mode

Select the category of data to specify.

### Settings

**Default:** Built in

**Built in**

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

**Fixed point**

Fixed-point data types.

**Enumerated**

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

## Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

## Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

## Dependency

Clicking the **Show data type assistant** button enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## See Also

See “Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

Controlengineers.ir

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

**Signed**

Specify the fixed-point data as signed.

**Unsigned**

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

## Settings

**Default:** 0

Binary points can be positive or negative integers.

## Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Slope

Specify slope for the fixed-point data type.

## Settings

**Default:**  $2^0$

Specify any positive real number.

## Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Output as nonvirtual bus

Output a nonvirtual bus.

### Settings

**Default:** Off

- On  
Output a nonvirtual bus.
- Off  
Output a virtual bus.

### Tips

- Select this option if you want code generated from this model to use a C structure to define the structure of the bus signal output by this block.
- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. Therefore, if you select this option all signals in the bus must have the same sample time. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Port dimensions

Specify the dimensions that a signal must have to connect to this Output block.

### Settings

**Default:** 1

Valid values are:

N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

### Dependency

Clearing **via bus object** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Signal type

Specify the numeric type of the signal output by this block.

### Settings

**Default:** real

real

Output a real-valued signal. The signal connected to this block must be real. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

complex

Output a complex signal. The signal connected to this block must be complex. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Characteristics

Dimensionalized	Yes
-----------------	-----

Multidimensionalized	Yes
Zero-Crossing Detection	No

## See Also

Argument Inport

Simulink Function

**Introduced in R2014b**

Controlengineers.ir

## Assertion

Check whether signal is zero

## Library

Model Verification

## Description

The Assertion block checks whether any of the elements of the input signal is zero. If all elements are nonzero, the block does nothing. If any element is zero, the block halts the simulation, by default, and displays an error message. Use the block parameter dialog box to:

- Specify that the block should display an error message when the assertion fails but allow the simulation to continue.
- Specify a MATLAB<sup>®</sup> expression to evaluate when the assertion fails.
- Enable or disable the assertion.

You can also use the **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box to enable or disable all Assertion blocks in a model.

The Assertion block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder™ generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Assertion block accepts input signals of any dimensions and any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable assertion

Clearing this check box disables the Assertion block, that is, causes the model to behave as if the Assertion block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box lets you enable or disable all Assertion blocks in a model regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Simulink software to terminate the simulation when the block input is zero. After terminating the simulation, the software displays an error. Clearing this check box causes the Simulink software to continue the simulation and display a warning when the block input is zero.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

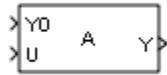

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Assignment

Assign values to specified elements of signal

## Library

Math Operations

## Description

The Assignment block assigns values to specified elements of the signal. You can specify the indices of the elements to be assigned values either by entering the indices in the block dialog box or by connecting an external indices source or sources to the block. The signal at the block data port, labeled U, specifies values to be assigned to Y. The block replaces the specified elements of Y with elements from the data signal.

Based on the value you enter for the **Number of output dimensions** parameter, a table of index options is displayed. Each row of the table corresponds to one of the output dimensions in **Number of output dimensions**. For each dimension, you can define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. When you configure the Assignment block for multidimensional signal operations, the block icon changes.

For example, assume a 5-D signal with a one-based index mode. The table in the Assignment block dialog changes to include one row for each dimension. If you define each dimension with the following entries:

- 1

**Index Option**, select Assign all

- 2

**Index Option**, select Index vector (dialog)

**Index**, enter [1 3 5]

- 3

**Index Option**, select Starting index (dialog)

**Index**, enter 4

- 4

**Index Option**, select Starting index (port)

- 5

**Index Option**, select Index vector (port)

The assigned values will be  $Y(1:end, [1 3 5], 4:3+size(U,3), Idx4:Idx4+size(U,4)-1, Idx5)=U$ , where  $Idx4$  and  $Idx5$  are the input ports for dimensions 4 and 5.

The Assignment block's data port is labeled U. The rest of this section refers to the data port as U to simplify the explanation of the block's usage.

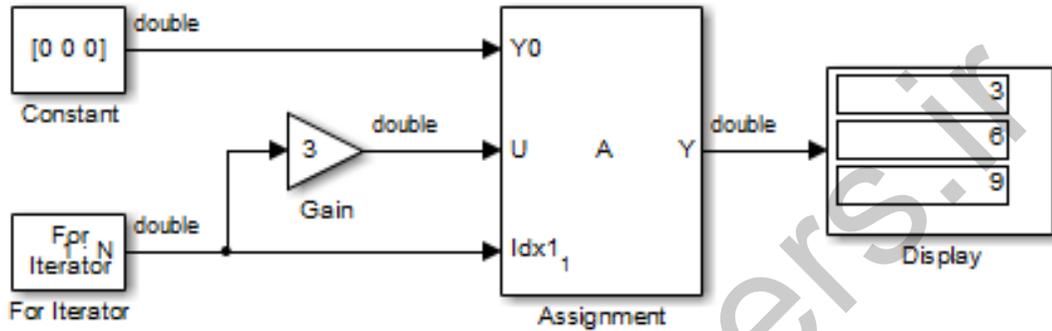

When using the Assignment block in Normal mode, Simulink initializes block outputs to zero even if the model does not explicitly initialize them. In Accelerator mode, Simulink converts the model into an S-Function. This involves code generation. The code generated may not do implicit initialization of block outputs. In such cases, you must explicitly initialize the model outputs.

You can use the block to assign values to vector, matrix, or multidimensional signals.

You can use an array of buses as an input signal to an Assignment block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Iterated Assignment

You can use the Assignment block to assign values computed in a For or While Iterator loop to successive elements of a vector, matrix, or multidimensional signal in a single time step. For example, the following model uses a For Iterator block to create a vector signal each of whose elements equals  $3*i$  where  $i$  is the index of the element.

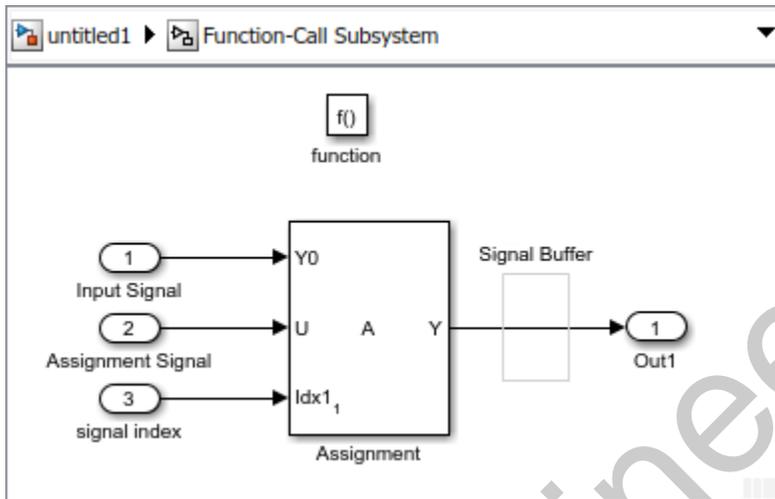

Iterated assignment uses an iterator (For or While) block to generate indices for the Assignment block. On the first iteration of an iterated assignment, the Assignment block copies the first input (Y0) to the output (Y) and assigns the second input (U) to the output Y(E<sub>1</sub>). On successive iterations, the Assignment block assigns the current value of U to Y(E<sub>i</sub>), that is, without first copying Y0 to Y. These actions occur in a single time step.

## Assignment Block in Conditional Subsystem

If you place an Assignment block in a conditional subsystem block, a signal buffer can be inserted in many cases, and merging of signals from Assignment blocks with partial writes can cause an error.

However, if you select the **Ensure output is virtual** check box for the conditional subsystem Output block, such cases are supported and partial writes to arrays using Assignment blocks are possible.

## Data Type Support

The data and initialization ports of the Assignment block accept signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. The external indices port accepts any built-in data type, except Boolean data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of output dimensions

Enter the number of dimensions of the output signal.

### Index mode

Select the indexing mode: **One-based** or **Zero-based**. If **One-based** is selected, an index of 1 specifies the first element of the input vector, 2, the second element, and so on. If **Zero-based** is selected, an index of 0 specifies the first element of the input vector, 1, the second element, and so on.

## Index Option

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

- Assign all

This is the default. All elements are assigned.

- Index vector (dialog)

Enables the **Index** column. Enter the indices of elements.

- Index vector (port)

Disables the **Index** column. The index port defines the indices of elements.

- Starting index (dialog)

Enables the **Index** column. Enter the starting index of the range of elements to be assigned values.

- Starting index (port)

Disables the **Index** column. The index port defines the starting index of the range of elements to be assigned values.

If you choose **Index vector (port)** or **Starting index (port)** for any dimension in the table, you can specify the value for the **Initialize output (Y)** parameter to be one of the following:

- Initialize using input port <Y0>
- Specify size for each dimension in table

Otherwise, Y0 always initializes output port Y.

The **Index** and **Output Size** columns are displayed as relevant.

## Index

If the **Index Option** is **Index vector (dialog)**, enter the index of each element you are interested in.

If the **Index Option** is **Starting index (dialog)**, enter the starting index of the range of elements to be selected. The number of elements from the starting point is determined by the size of this dimension at U.

### Output Size

Enter the width of the block output signal. If you select **Specify size for each dimension in table** for the **Initialize output (Y)** parameter, this column is enabled.

### Initialize output (Y)

Specify how to initialize the output signal. The **Initialize output** parameter appears when you set **Index Option** to **Index vector (port)** or **Starting index (port)**.

- Initialize using input port <Y0>

The signal at the input port Y0 initializes the output.

- Specify size for each dimension in table

The block requires you to specify the width of the block's output signal in the **Output Size** parameter. If the output has unassigned elements, the value of those elements is undefined.

### Action if any output element is not assigned

Specify whether to produce a warning or error if you have not assigned all output elements. Options include:

- Error — Simulink software terminates the simulation and displays an error.
- Warning — Simulink software displays a warning and continues the simulation.
- None — Simulink software takes no action.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Backlash

Model behavior of system with play

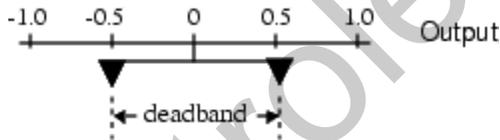

## Library

Discontinuities

## Description

The Backlash block implements a system in which a change in input causes an equal change in output. However, when the input changes direction, an initial change in input has no effect on the output. The amount of side-to-side play in the system is referred to as the *deadband*. The deadband is centered about the output. This figure shows the block's initial state, with the default deadband width of 1 and initial output of 0.

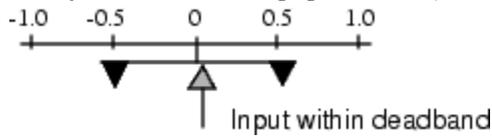

A system with play can be in one of three modes:

- Disengaged — In this mode, the input does not drive the output and the output remains constant.
- Engaged in a positive direction — In this mode, the input is increasing (has a positive slope) and the output is equal to the input *minus* half the deadband width.
- Engaged in a negative direction — In this mode, the input is decreasing (has a negative slope) and the output is equal to the input *plus* half the deadband width.

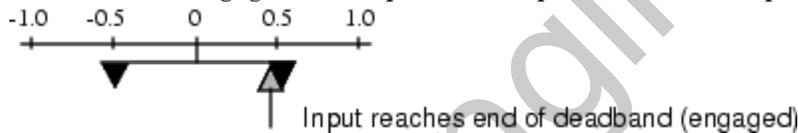

If the initial input is outside the deadband, the **Initial output** parameter value determines whether the block is engaged in a positive or negative direction, and the output at the start of the simulation is the input plus or minus half the deadband width.

For example, the Backlash block can be used to model the meshing of two gears. The input and output are both shafts with a gear on one end, and the output shaft is driven by the input shaft. Extra space between the gear teeth introduces *play*. The width of this spacing is the **Deadband width** parameter. If the system is disengaged initially, the output (the position of the driven gear) is defined by the **Initial output** parameter.

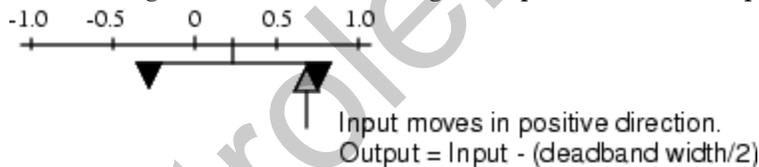

The following figures illustrate the block's operation when the initial input is within the deadband. The first figure shows the relationship between the input and the output while the system is in disengaged mode (and the default parameter values are not changed).

The next figure shows the state of the block when the input has reached the end of the deadband and engaged the output. The output remains at its previous value.

The final figure shows how a change in input affects the output while they are engaged.

If the input reverses its direction, it disengages from the output. The output remains constant until the input either reaches the opposite end of the deadband or reverses its direction again and engages at the same end of the deadband. Now, as before, movement in the input causes equal movement in the output.

For example, if the deadband width is 2 and the initial output is 5, the output,  $y$ , at the start of the simulation is as follows:

- 5 if the input,  $u$ , is between 4 and 6
- $u + 1$  if  $u < 4$
- $u - 1$  if  $u > 6$

## Data Type Support

The Backlash block accepts and outputs real values of `single`, `double`, and built-in integer data types.

## Parameters

### Deadband width

Specify the width of the deadband. The default is 1.

### Initial output

Specify the initial output value. The default value is 0. This parameter is tunable. Simulink does not allow the initial output of this block to be `inf` or `NaN`.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox™ license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

---

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u. All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

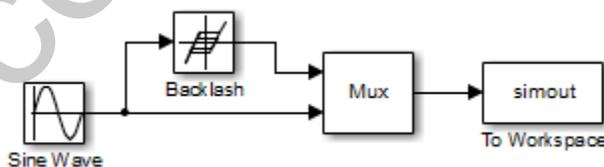

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

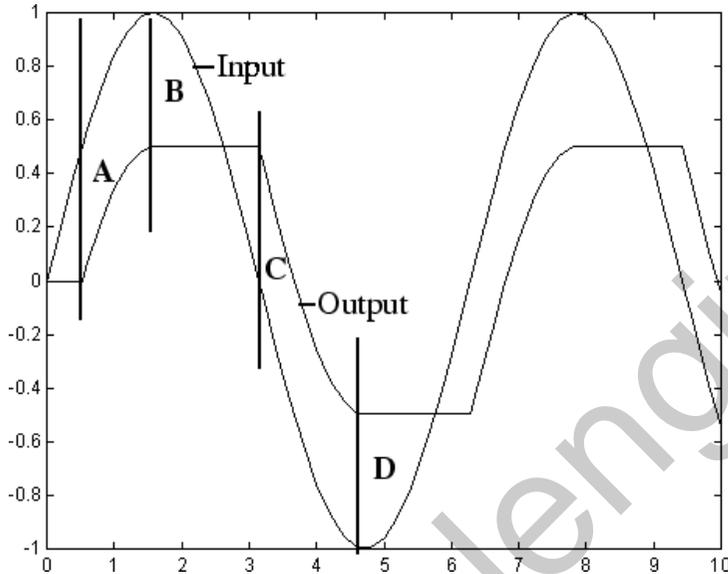

---

## Examples

The following model shows the effect of a sine wave passing through a Backlash block.

The Backlash block uses default parameter values: the deadband width is 1 and the initial output is 0. The following plot shows that the Backlash block output is zero until the input reaches the end of the deadband (at 0.5). Now the input and output are engaged and the output moves as the input does until the input changes direction (at 1.0). When the input reaches 0, it again engages the output at the opposite end of the deadband.

- A** Input engages in positive direction. Change in input causes equal change in output.
- B** Input disengages. Change in input does not affect output.
- C** Input engages in negative direction. Change in input causes equal change in output.
- D** Input disengages. Change in input does not affect output.

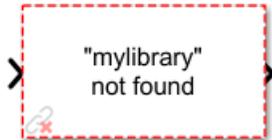

## Characteristics

Data Types	Double   Single   Base Integer
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

## Unresolved Link

Indicate unresolved reference to library block

## Description

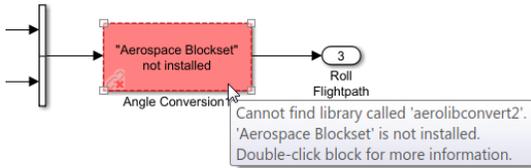

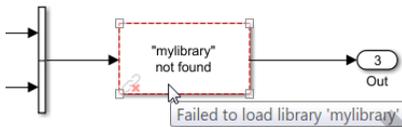

This block indicates an unresolved reference to a library block (see “Linked Blocks”). You can use this block's parameter dialog box to fix the reference to point to the actual location of the library block.

## Parameters

### Details

The **Details** field contains a description of the cause of the unresolved link. Simulink tries to help you find and install missing products that a model needs to run. For missing products, the block description provides a link. Click the link to open Add-On Explorer and install the missing products.

# 1 Blocks – Alphabetical List

You can customize the Unresolved Link block description for your library to include URLs as follows:

```
set_param(library1,'libraryinfo','https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

### Source block

Path of the library block that this link represents. To fix a bad link, either click the link in the description to open Add-On Explorer and install a missing product, or edit the **Source block** field to the correct path of the library block. Then select Apply or OK to apply the fix and close the dialog box.

Alternatively, to fix an unresolved link, you can:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.

### Source type

Type of library block that this link represents.

# Band-Limited White Noise

Introduce white noise into continuous system

## Library

Sources

## Description

### Simulation of White Noise

The Band-Limited White Noise block generates normally distributed random numbers that are suitable for use in continuous or hybrid systems.

Theoretically, continuous white noise has a correlation time of 0, a flat power spectral density (PSD), and a total energy of infinity. In practice, physical systems are never disturbed by white noise, although white noise is a useful theoretical approximation when the noise disturbance has a correlation time that is very small relative to the natural bandwidth of the system.

In Simulink software, you can simulate the effect of white noise by using a random sequence with a correlation time much smaller than the shortest time constant of the system. The Band-Limited White Noise block produces such a sequence. The correlation time of the noise is the sample rate of the block. For accurate simulations, use a correlation time much smaller than the fastest dynamics of the system. You can get good results by specifying

$$tc \approx \frac{1}{100} \frac{2\pi}{f_{max}}$$

where  $f_{max}$  is the bandwidth of the system in rad/sec.

## Comparison with the Random Number Block

The primary difference between this block and the Random Number block is that the Band-Limited White Noise block produces output at a specific sample rate. This rate is related to the correlation time of the noise.

## Usage with the Averaging Power Spectral Density Block

The Band-Limited White Noise block specifies a two-sided spectrum, where the units are Hz. The Averaging Power Spectral Density block specifies a one-sided spectrum, where the units are the square of the magnitude per unit radial frequency:  $\text{Mag}^2/(\text{rad}/\text{sec})$ . When you feed the output of a Band-Limited White Noise block into an Averaging Power Spectral Density block, the average PSD value is  $\pi$  times smaller than the **Noise power** of the Band-Limited White Noise block. This difference is the result of converting the units of one block to the units of the other:  $1/(1/2)(2\pi) = 1/\pi$ , where:

- $1/2$  is the factor for converting from a two-sided to one-sided spectrum
- $2\pi$  is the factor for converting from Hz to rad/sec

## Algorithm

To produce the correct intensity of this noise, the covariance of the noise is scaled to reflect the implicit conversion from a continuous PSD to a discrete noise covariance. The appropriate scale factor is  $1/tc$ , where  $tc$  is the correlation time of the noise. This scaling ensures that the response of a continuous system to the approximate white noise has the same covariance as the system would have to true white noise. Because of this scaling, the covariance of the signal from the Band-Limited White Noise block is not the same as the **Noise power** (intensity) parameter. This parameter is actually the height of the PSD of the white noise. This block approximates the covariance of white noise as the **Noise power** divided by  $tc$ .

## Data Type Support

The Band-Limited White Noise block outputs real values of type **double**.

## Parameters

### Noise power

Specify the height of the PSD of the white noise. The default value is 0.1.

### Sample time

Specify the correlation time of the noise. The default value is 0.1. For more information, see “Specify Sample Time” in the Simulink documentation.

### Seed

Specify the starting seed for the random number generator. The default value is 23341.

### Interpret vector parameters as 1-D

Select to output a 1-D array when the block parameters are vectors. Otherwise, output a 2-D array one of whose dimensions is 1. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

## Examples

The following Simulink examples show how to use the Band-Limited White Noise block:

- `slexAircraftExample`
- `sldemo_radar_eml`

## Characteristics

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No

## Bias

Add bias to input

## Library

Math Operations

## Description

The Bias block adds a bias, or offset, to the input signal according to  $Y = U + bias$ ,

where  $U$  is the block input and  $Y$  is the output.

## Data Type Support

The Bias block accepts and outputs real or complex values of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

**Bias**

Specify the value of the offset to add to the input signal.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can

detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point

## Bit Clear

Set specified bit of stored integer to zero

## Library

Logic and Bit Operations

## Description

The Bit Clear block sets the specified bit, given by its index, of the stored integer to zero. Scaling is ignored.

You can specify the bit to be set to zero with the **Index of bit** parameter, where bit zero is the least significant bit.

## Data Type Support

The Bit Clear block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

## Parameters

### Index of bit

Index of bit where bit 0 is the least significant bit.

## Examples

If the Bit Clear block is turned on for bit 2, bit 2 is set to 0. A vector of constants  $2.^{[0 \ 1 \ 2 \ 3 \ 4]}$  is represented in binary as [00001 00010 00100 01000 10000]. With bit 2 set to 0, the result is [00001 00010 00000 01000 10000], which is represented in decimal as [1 2 0 8 16].

## Characteristics

Data Types	Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

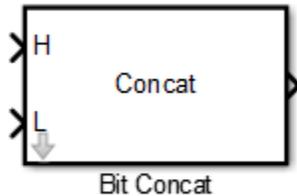

## See Also

Bit Set

Introduced before R2006a

## Bit Concat

Concatenates up to 128 input words into single output

## Library

HDL Coder / HDL Operations

## Description

The Bit Concat block concatenates up to 128 input words into a single output. The input port labeled L designates the lowest-order input word. The port labeled H designates the highest-order input word. The right-to-left ordering of words in the output follows the low-to-high ordering of input signals.

How the block operates depends on the number and dimensions of the inputs, as follows:

- Single input: The input is a scalar or a vector. When the input is a vector, the coder concatenates the individual vector elements.
- Two inputs: Inputs are any combination of scalar and vector. When one input is scalar and the other is a vector, the coder performs scalar expansion. Each vector element is concatenated with the scalar, and the output has the same dimension as the vector. When both inputs are vectors, they must have the same size.
- Three or more inputs (up to a maximum of 128 inputs): Inputs are uniformly scalar or vector. All vector inputs must have the same size.

## Parameters

**Number of Inputs:** Enter an integer specifying the number of input signals. The number of block input ports updates when you change **Number of Inputs**.

- Default: 2
- Minimum: 1
- Maximum: 128

---

**Caution:** Make sure that the **Number of Inputs** is equal to the number of signals you connect to the block. If the block has unconnected inputs, an error occurs at code generation time.

---

## Ports

The block has up to 128 input ports, with H representing the highest-order input word, and L representing the lowest-order input word. The maximum concatenated output word size is 128 bits.

## Supported Data Types

- Input: Fixed-point, integer (signed or unsigned), Boolean
- Output: Unsigned fixed-point or integer

## Bit Reduce

AND, OR, or XOR bit reduction on all input signal bits to single bit

## Library

HDL Coder / HDL Operations

## Description

The Bit Reduce block performs a selected bit-reduction operation (AND, OR, or XOR) on all the bits of the input signal, for a single-bit result.

## Parameters

### Reduction Mode

Specifies the reduction operation:

- AND (default): Perform a bitwise AND reduction of the input signal.
- OR: Perform a bitwise OR reduction of the input signal.
- XOR: Perform a bitwise XOR reduction of the input signal.

## Ports

The block has the following ports:

### Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

### Output

Supported data type: `ufix1`

## Bit Rotate

Rotate input signal by bit positions

## Library

HDL Coder / HDL Operations

## Description

The Bit Rotate block rotates the input signal left or right by the specified number of bit positions.

## Parameters

**Rotate Mode:** Specifies direction of rotation, left or right. The default is `Rotate Left`.

**Rotate Length:** Specifies the number of bits to rotate. Specify a value greater than or equal to zero. The default is 0.

## Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

#### Output

Has the same data type as the input signal.

## Bit Set

Set specified bit of stored integer to one

## Library

Logic and Bit Operations

## Description

The Bit Set block sets the specified bit of the stored integer to one. Scaling is ignored.

You can specify the bit to be set to one with the **Index of bit** parameter, where bit zero is the least significant bit.

## Data Type Support

The Bit Set block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

## Parameters

### Index of bit

Index of bit where bit 0 is the least significant bit.

## Examples

If the Bit Set block is turned on for bit 2, bit 2 is set to 1. A vector of constants  $2.^{[0 \ 1 \ 2 \ 3 \ 4]}$  is represented in binary as [00001 00010 00100 01000 10000]. With bit 2 set to 1,

the result is [00101 00110 00100 01100 10100], which is represented in decimal as [5 6 4 12 20].

## Characteristics

Data Types	Boolean   Base Integer   Fixed-Point

## Bit Shift

Logical or arithmetic shift of input signal

## Library

HDL Coder / HDL Operations

## Description

The Bit Shift block performs a logical or arithmetic shift on the input signal.

## Parameters

### Shift Mode

Default: Shift Left Logical

Specifies the type and direction of shift:

- Shift Left Logical (default)
- Shift Right Logical
- Shift Right Arithmetic

### Shift Length

Specifies the number of bits to be shifted. Specify a value greater than or equal to zero. The default is 0.

## Ports

The block has the following ports:

### Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

### Output

Has the same data type and bit width as the input signal.

## See Also

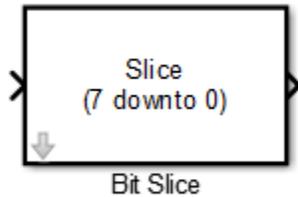

### See Also

Bit Rotate | Bit Concat | Bit Reduce | Bit Slice

Introduced in R2014a

## Bit Slice

Return field of consecutive bits from input signal

## Library

HDL Coder / HDL Operations

## Description

The Bit Slice block returns a field of consecutive bits from the input signal. Specify the lower and upper boundaries of the bit field by using zero-based indices in the **LSB Position** and **MSB Position** parameters.

## Parameters

### MSB Position

Specifies the bit position (zero-based) of the most significant bit (MSB) of the field to extract. The default is 7.

For an input word size **WS**, **LSB Position** and **MSB Position** must satisfy the following constraints:

```
WS > MSB Position >= LSB Position >= 0;
```

The word length of the output is computed as (MSB Position - LSB Position) + 1.

### LSB Position

Specifies the bit position (zero-based) of the least significant bit (LSB) of the field to extract. The default is 0.

## Ports

The block has the following ports:

### Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Maximum bit width: 128

### Output

Supported data types: unsigned fixed-point or unsigned integer.

# Bitwise Operator

Specified bitwise operation on inputs

## Library

Logic and Bit Operations

## Description

### Bitwise Operations

The Bitwise Operator block performs the bitwise operation that you specify on one or more operands. Unlike logic operations of the Logical Operator block, bitwise operations treat the operands as a vector of bits rather than a single value.

You can select one of the following bitwise operations:

Bitwise Operation	Description
AND	TRUE if the corresponding bits are all TRUE
OR	TRUE if at least one of the corresponding bits is TRUE
NAND	TRUE if at least one of the corresponding bits is FALSE
NOR	TRUE if no corresponding bits are TRUE
XOR	TRUE if an odd number of corresponding bits are TRUE
NOT	TRUE if the input is FALSE (available only for single input)

## Restrictions on Block Operations

The Bitwise Operator block does not support shift operations. For shift operations, use the Shift Arithmetic block.

When configured as a multi-input XOR gate, this block performs modulo-2 addition according to the IEEE® Standard for Logic Elements.

## Behavior of Inputs and Outputs

The output data type, which the block inherits from the driving block, must represent zero exactly. Data types that satisfy this condition include signed and unsigned integer data types.

The size of the block output depends on the number of inputs, the vector size, and the operator you select:

- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the bitwise logical complements of the input vector elements.
- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector.
  - If you do not specify a bit mask, the output is a scalar.
  - If you do specify a bit mask, the output is a vector.
- For two or more inputs, the block performs the operation between all of the inputs. If the inputs are vectors, the block performs the operation between corresponding elements of the vectors to produce a vector output.

## Bit Mask Behavior

Block behavior changes depending on whether you use a bit mask.

If the Use bit mask check box is...	The block accepts...	And you specify...	By using...
Selected	One input	<b>Bit Mask</b>	Any valid MATLAB expression, such as $2^5+2^2+2^0$ for the bit mask 00100101

If the Use bit mask check box is...	The block accepts...	And you specify...	By using...
Not selected	Multiple inputs, all having the same base data type	<b>Number of input ports</b>	Any positive integer greater than 1

**Tip:** You can also use character vectors to specify a hexadecimal bit mask such as {'FE73', '12AC'}.

## Bit Set and Bit Clear Operations

You can use the bit mask to set or clear a bit on the input.

To perform a...	Set the Operator parameter to...	And create a bit mask with...
Bit set	OR	A 1 for each corresponding input bit that you want to set to 1
Bit clear	AND	A 0 for each corresponding input bit that you want to set to 0

Suppose you want to set the fourth bit of an 8-bit input vector. The bit mask would be 00010000, which you can specify as  $2^4$  for the **Bit Mask** parameter. To clear the bit, the bit mask would be 11101111, which you can specify as  $2^7+2^6+2^5+2^3+2^2+2^1+2^0$  for the **Bit Mask** parameter.

## Data Type Support

The Bitwise Operator block supports the following data types:

- Built-in integer
- Fixed point
- Boolean

The block does not support floating-point data types or enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Operator

Specify the bitwise logical operator for the block operands.

### Use bit mask

Select to use the bit mask. Clearing this check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

### Number of input ports

Specify the number of inputs. The default value is 1.

### Bit Mask

Specify the bit mask to associate with a single input. This parameter is available only when you select **Use bit mask**.

---

**Tip:** Do not use a mask greater than 53 bits. Otherwise, an error message appears during simulation.

---

### Treat mask as

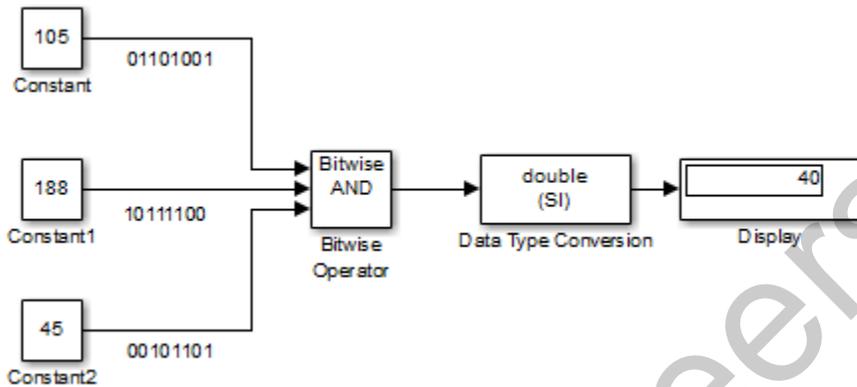

Specify whether to treat the mask as a real-world value or a stored integer. This parameter is available only when you select **Use bit mask**.

The encoding scheme is  $V = SQ + B$ , as described in “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation. **Real World Value** treats the mask as  $V$ . **Stored Integer** treats the mask as  $Q$ .

## Examples

### Unsigned Inputs for the Bitwise Operator Block

The following model shows how the **Bitwise Operator** block works for unsigned inputs.

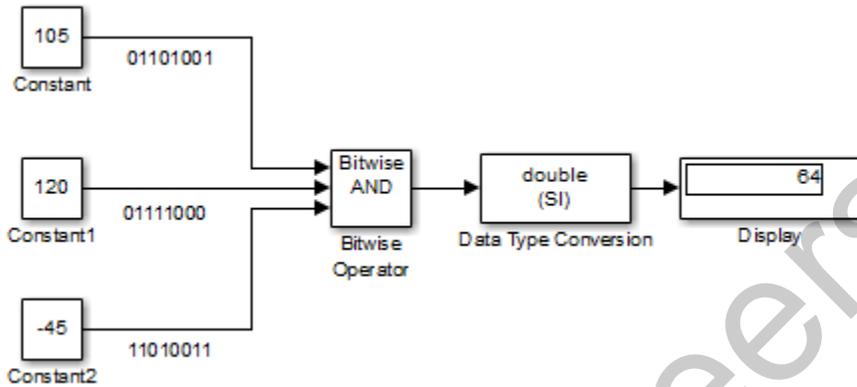

Each Constant block outputs an 8-bit unsigned integer (`uint8`). To determine the binary value of each Constant block output, use the `dec2bin` function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	00101000	40
OR	11111101	253
NAND	11010111	215
NOR	00000010	2
XOR	11111000	248
NOT	N/A	N/A

## Signed Inputs for the Bitwise Operator Block

The following model shows how the Bitwise Operator block works for signed inputs.

Each Constant block outputs an 8-bit signed integer (`int8`). To determine the binary value of each Constant block output, use the `dec2bin` function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	01000000	64
OR	11111011	-5
NAND	10111111	-65
NOR	00000100	4
XOR	11000010	-62
NOT	N/A	N/A

## Characteristics

Data Types	Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block

# Bus Assignment

Replace specified bus elements

## Library

Signal Routing

## Description

To assign the values of a signal to bus element, you can use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

The Bus Assignment block assigns signals connected to its assignment input ports (:=) to specified elements of the bus connected to its bus input port. The block replaces the signals previously assigned to those elements. The change does not affect the composition of the bus; it affects only the values of the signals themselves. Signals not replaced are unaffected by the replacement of other signals. You cannot use the Bus Assignment block to replace a bus that is nested within an array of buses.

Use the Block Parameters dialog box to specify the bus elements to be replaced. The block displays an assignment input port for each such element. The signal connected to the assignment port must have the same structure, data type, and sample time as the bus element to which it corresponds. You can use a **Rate Transition** block to change the sample time of an individual signal or signals in a bus, to include the signal or bus in a nonvirtual bus. See “Virtual and Nonvirtual Buses” for more information.

By default, Simulink repairs broken selections in the Bus Assignment Block Parameters dialog boxes that are due to upstream bus hierarchy changes. Simulink generates a

warning to highlight that it modified the model. To prevent Simulink from making these repairs automatically, in the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the “Repair bus selections” diagnostic to **Error without repair**.

When using arrays of buses with a Bus Assignment block, these limitations apply:

- You can assign or replace a subbus that is an array of buses. However, the nested bus cannot be nested inside an array of buses.
- To replace a signal in an array of buses, use a Selector block to select the index for the bus element that you want to use with the Bus Assignment block. Then use that selected bus element with the Bus Assignment block.

## Data Type Support

The bus input port of the Bus Assignment block accepts real or complex values of any data type that Simulink supports, including fixed-point and enumerated data types. The assignment input ports accept the same data types as the bus elements to which they correspond. The Bus Assignment block outputs real or complex values of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Signals in the bus

Displays the names of the signals contained by the bus connected to the bus input port. Click any item in the list to select it. To find the source of the selected signal, click **Find**. Simulink opens and highlights the system containing the signal source.

To move the currently selected signal into the adjacent list of signals to be assigned values (see **Signals that are being assigned** below), click **Select>>**. To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

### Signals that are being assigned

Lists the names of bus elements to be assigned values. This block displays an assignment input port for each bus element in this list. The label of the corresponding input port contains the name of the element. You can order the signals

by using the **Up**, **Down**, or **Remove**. Port connectivity is maintained when you change the signal order.

Three question marks (???) before the name of a bus element indicate that the input bus no longer contains an element of that name. This situation can occur because the bus has changed since the last time you refreshed the Bus Assignment block input and bus element assignment lists. To address this issue, either modify the bus to include a signal of the specified name or remove the name from the list of bus elements to be assigned values.

### Enable regular expression

To display this parameter, click the **Options** button on the right-hand side of the **Filter by name** edit box (.

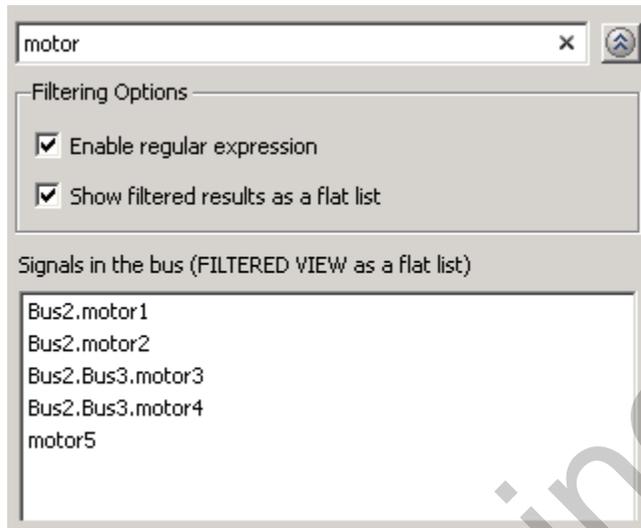

Enables the use of MATLAB regular expressions for filtering signal names. For example, entering **t\$** in the **Filter by name** edit box displays all signals whose names end with a lowercase **t** (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

The default is **On**. If you disable use of MATLAB regular expressions for filtering signal names, filtering treats the text you enter in the **Filter by name** edit box as a literal character vector.

### Show filtered results as a flat list

To display this parameter, click the **Options** button on the right-hand side of the **Filter by name** edit box (.

Uses a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box. The flat list format uses dot notation to reflect the hierarchy of bus signals. For example, here is the flat list format for a filtered set of nested bus signals.

The default is Off, which displays the filtered list using a tree format.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

## Bus Creator

Create signal bus

## Library

Signal Routing

## Description

The Bus Creator block combines a set of signals into a bus. To bundle a group of signals with a Bus Creator block, set the block parameter **Number of inputs** to the number of signals in the group. The block displays the number of ports that you specify. Connect to the resulting input ports those signals that you want to group.

The signals in the bus are ordered from the top input port to the bottom input port. See “Port Location After Rotating or Flipping” in for a description of the port order for various block orientations.

You can connect any type of signal to the inputs, including other bus signals. To ungroup bus signals, connect the output port of the block to a Bus Selector block port.

---

**Note:** Simulink hides the name of a Bus Creator block when you copy it from the Simulink library to a model.

---

For information about using this block in a library block, see “Buses and Libraries”.

You can use an array of buses as an input signal to a Bus Creator block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

---

**Tip:** For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
  - Make it easier to change the interface incrementally.
  - Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.
- 

## Bus Signal Naming

The Bus Creator block assigns a name to each signal on the bus that it creates. You can then refer to signals by name when you are searching for their sources (see “Browse Bus Signals” on page 1-105) or selecting signals for connection to other blocks.

Specify one of the following signal naming options:

- Each signal on the bus inherits the name of the signal connected to the bus (the default).

Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (`signal#`) to all input signal names, where `#` is the input port index.

The Bus Creator block generates names for bus signals whose corresponding inputs do not have names. The names are in the form `signaln`, where `n` is the number of the port the input signal connects to.

- Each input signal must have a specific name.
- If the bus output data type is a bus object, bus signal names use the corresponding bus object element names.

You can change the name of any signal by editing the name on the block diagram or in the Signal Properties dialog box. If you change the signal name while the Bus Creator Block Parameters dialog box is open, to see the updated name in the dialog box, click **Refresh**.

## Bus Object as the Output Data Type

You can use a bus object as the bus output data type for a Bus Creator block. Using a bus object can provide strong data typing with an explicit signal interface. Model referencing requires using bus objects for bus signals that cross model reference boundaries. For more information, see “When to Use Bus Objects”.

To create a nonvirtual bus using a Bus Creator block, use the following settings.

- For the **Output data type** parameter, use a bus object.
- Select **Output as nonvirtual bus**.

To use a bus object to enforce strong data typing, clear the **Override bus signal names from inputs** check box.

## Browse Bus Signals

The **Signals in the bus** list on a Bus Creator Block Parameters dialog box displays a list of the signals entering the block. An arrow next to a signal indicates that the signal is itself a bus. To display the contents of the bus, click the arrow. In this way, you can view all signals entering the block, including the signals entering via buses.

To find the source of any signal entering the block, select the signal in the **Signals in the bus** list and click the adjacent **Find** button. Simulink opens the subsystem containing the signal source, if necessary, and highlights the icon of the source.

## Reorder, Add, or Remove Signals

To rearrange the signals that the Bus Creator block includes in the bus signal that it produces, use buttons such as **Add**.

You can select multiple contiguous signals in the **Signals in the bus** list to reorder or remove. You cannot rearrange leaf signals within a bus. For example, you can move bus signal BUS1 up or down in the list, but you cannot reorder any of the bus elements of BUS1.

After making your edits, click **Apply**.

## Data Type Support

The Bus Creator block accepts and outputs real or complex values of any data type supported by Simulink, including fixed-point and enumerated data types, as well as bus objects.

For a discussion on the data types supported by Simulink, refer to “Data Types Supported by Simulink”.

If you change elements or the order of elements in the Bus Creator block and the incoming bus is a nonvirtual bus, Simulink reports inconsistency errors when you compile the model.

## Parameters

- “Number of inputs” on page 1-107
- “Signals in the bus” on page 1-108
- “Enable regular expression” on page 1-109
- “Show filtered results as a flat list” on page 1-110
- “Output data type” on page 1-111
- “Show data type assistant” on page 1-112
- “Mode” on page 1-113
- “Output as nonvirtual bus” on page 1-114
- “Override bus signal names from inputs” on page 1-115
- “Require input signal names to match signals above” on page 1-116
- “Rename selected signal” on page 1-116

## Number of inputs

Specify the number of input ports on this block.

### Settings

**Default:** 2

To create ports for input signals for the Bus Creator block, specify a number.

---

**Tip:** In the Simulink Editor, as you draw a new signal line close to input side of a virtual Bus Creator block, if all input ports are already connected:

- Adds another input port to the Bus Creator block
  - Updates the **Number of inputs** parameter
  - Add to the list of bus signals a signal name for the new signal.
- 

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Signals in the bus

Show the input signals for the bus.

### Settings

When you modify the **Number of inputs** parameter, click **Refresh** to update the list of signals.

### Tips

- An arrow next to a signal name indicates that the signal is itself a bus. To display the subsidiary bus signals, click the arrow.
- Click the **Refresh** button to update the list after editing the name of an input signal.
- Click the **Find** button to highlight the source of the currently selected signal.
- To rearrange signals in the bus, see “Reorder, Add, or Remove Signals” on page 1-105.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable regular expression

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering **t\$** in the **Filter by name** edit box displays all signals whose names end with a lowercase **t** (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

### Settings

**Default:** On

On

Allow use of MATLAB regular expressions for filtering signal names.

Off

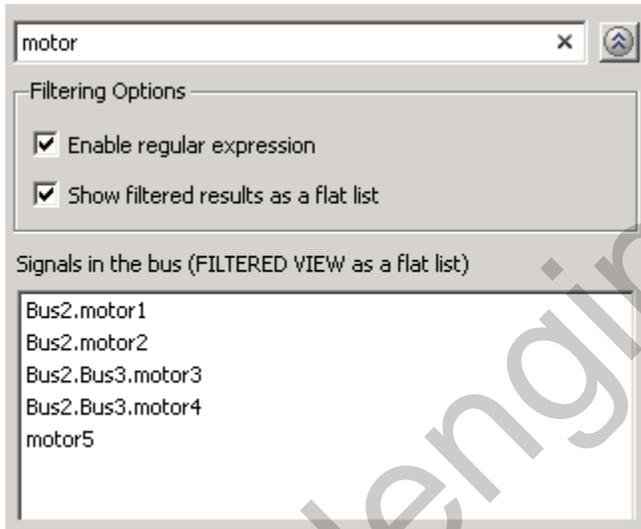

Disable use of MATLAB regular expressions for filtering signal names. Filtering treats the text you enter in the **Filter by name** edit box as a literal character vector.

### Dependencies

Selecting the **Options** button on the right-hand side of the **Filter by name** edit box  enables this parameter.

## Show filtered results as a flat list

Uses a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box. The flat list format uses dot notation to reflect the hierarchy of bus signals. The following is an example of a flat list format for a filtered set of nested bus signals.

### Settings

**Default:** Off

On

Display the filtered list of signals using a flat list format, indicating bus hierarchies with dot notation instead of using a tree format.

Off

Display filtered bus hierarchies using a tree format.

### Dependencies

Selecting the **Options** button on the right-hand side of the **Filter by name** edit box () enables this parameter.

## Output data type

Specify the output data type of the external input.

### Settings

**Default:** Inherit: auto

**Inherit:** auto

A rule that inherits a data type

**Bus:** <object name>

Data type is a bus object.

### Tips

- Determine whether you want the Bus Creator block to output a virtual or nonvirtual bus.
  - For a virtual bus, use the **Output data type** parameter default (Inherit: auto) or set the parameter to specify a bus object using Bus: <object name>.
  - For a nonvirtual bus, set the **Output data type** parameter to specify a bus object using Bus: <object name> and click **Output as nonvirtual bus**.
- If you specify a bus object as the output data type, to match bus signal names with the corresponding bus object element names, clear the **Override bus signal names from inputs** check box.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

## Settings

### Default: Inherit

#### Inherit

Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right.

#### Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

## Tip

During simulation or update diagram, Simulink checks whether the signals connected to this Bus Creator block have the specified structure. If not, Simulink displays an error message.

## Dependency

Clicking the **Show data type assistant** button enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## See Also

See “Specify Data Types Using Data Type Assistant”.

## Output as nonvirtual bus

Output a nonvirtual bus.

### Settings

**Default:** Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

### Tips

- To have code generated from this model use a C structure to define the structure of the bus signal output by this block, select this option.
- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. Therefore, if you select this option all signals entering the Bus Creator block must have the same sample time. To include the signal or bus in a nonvirtual bus, use a Rate Transition block to change the sample time of signals in a bus.

### Dependencies

The following **Data type** values enable this parameter:

- Bus: <object name>
- <data type expression> that specifies a bus object

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Override bus signal names from inputs

Override bus signal names from input signals or inherit names from the bus object elements.

### Settings

Default: On

On

Override bus element names from input signal names.

Off

Inherit bus signal names from the corresponding element names in the bus object.

### Tips

- To inherit signal names from bus element names, clear the **Override bus signal names from inputs** check box. This approach:
  - Enforces strong data typing.
  - Avoids having to enter a signal name multiple times: in the bus object and in the model. Entering the name multiple times can accidentally create signal name mismatches.
  - Supports the array of buses requirement to have consistent signal names across array elements.
- Alternatively, you can enforce strong data typing and also check that input signal names match the bus object element names.
  - Select the **Override bus signal names from inputs** check box.
  - Set the **Configuration Parameters > Diagnostics > Connectivity > Element name mismatch** parameter to **error**.

### Dependencies

The **Output data type** parameter must be set to a bus object.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Require input signal names to match signals above

Require that input signals have the names listed in the **Signals in the bus** list.

### Settings

**Default:** Off

On

Check that the input signal names match the signal names in the Bus Creator block parameters dialog boxes.

Off

Does not check that the input signal names match the signal names in the Bus Creator block parameters dialog box.

### Tips

- The **Require input signal names to match signals above** option might be removed in a future release. To enforce strong data typing, see the Bus Creator block parameter “Override bus signal names from inputs” on page 1-115.
- If you select **Override bus signal names from inputs**, the **Require input signal names to match signals above** setting is ignored.

## Rename selected signal

List the name of the signal currently selected in the **Signals in the bus** list when you select **Require input signal names to match signals above**.

### Settings

**Default:** ' '

Edit this field to change the name of the currently selected signal. See “Signal Names and Labels” for guidelines for signal names.

### Dependencies

Selecting **Require input signal names to match signals above** enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Examples

For an example of how the Bus Creator block works, see the `busdemo` model.

## Characteristics

Data types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional signals	Yes
Variable-size signals	Yes
Code generation	Yes

## See Also

## Bus Selector

Select signals from incoming bus

### Library

Signal Routing

### Description

The Bus Selector block outputs a specified subset of the elements of the bus at its input. The block can output the specified elements as separate signals or as a new bus.

---

**Note** Simulink software hides the name of a Bus Selector block when you copy it from the Simulink library to a model.

---

By default, Simulink implicitly converts a nonbus signal to a bus signal to support connecting the signal to a Bus Selector block. To prevent Simulink from performing that conversion, in the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the “Non-bus signals treated as bus signals” diagnostic to **warning** or **error**.

When the block outputs separate elements, it outputs each element from a separate port from top to bottom of the block. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

In the Simulink Editor, as you draw a new signal line close to output side of a Bus Selector block and all output ports are already connected, Simulink:

- Adds a port
- Prompts you to specify the signal to be selected

You cannot use this automatic port addition approach in either of these cases:

- There is no bus input signal connected to the Bus Selector block.
- You do not specify a signal in response to the prompt that appears when you draw a signal line close to the Bus Selector block icon.
- You select the **Output as bus** parameter.

---

**Tip:** For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
  - Make it easier to change the interface incrementally.
  - Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.
- 

## Reorder or Remove Signals

To reorder the selected signals that the Bus Selector block includes in the bus signal that it produces, click **Up**, **Down**, or **Remove**.

You can select multiple contiguous signals in the **Signals in the bus** list to remove or reorder.

You cannot rearrange leaf signals within a bus. For example, you can move bus signal BUS1 up or down in the list, but you cannot reorder any of the bus elements of BUS1.

After you click a button, click **Apply**.

## Array of Buses Support

When using arrays of buses with a Bus Selector block, these limitations apply:

- You cannot connect an array of buses signal to a Bus Selector block. To work with an array of buses signal, select with a Selector block the index for the bus element that you want to use with the Bus Selector block. Then use that selected bus element with the Bus Selector block.

- You cannot assign into a subbus that is an array of buses.

## Data Type Support

A Bus Selector block accepts and outputs real or complex values of any data type supported by Simulink software, including fixed-point and enumerated data types.

For a discussion on the data types supported by Simulink software, see “Data Types Supported by Simulink”.

## Parameters

### Signals in the bus

Shows the signals in the input bus.

#### Settings

To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

#### Tips

- Use **Select>>** to select signals to output.
- To find the source of any signal entering the block, select the signal in the list and click **Find**. The Simulink software opens and highlights the system containing the signal source.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable regular expression

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

### Settings

**Default:** On

On

Allow use of MATLAB regular expressions for filtering signal names.

Off

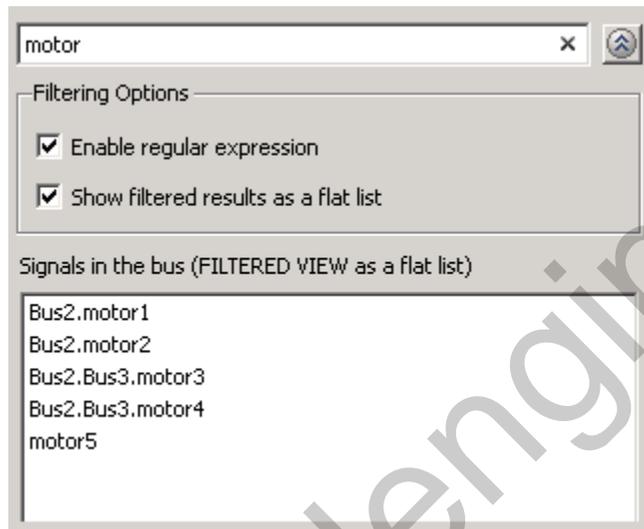

Disable use of MATLAB regular expressions for filtering signal names. Filtering treats the text you enter in the **Filter by name** edit box as a literal character vector.

### Dependencies

Selecting the **Options** button on the right-hand side of the **Filter by name** edit box () enables this parameter.

## Show filtered results as a flat list

Uses a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box. The flat list format uses dot notation to reflect the hierarchy of bus signals. The following is an example of a flat list format for a filtered set of nested bus signals.

### Settings

**Default:** Off

On

Display the filtered list of signals using a flat list format, indicating bus hierarchies with dot notation instead of using a tree format.

Off

Display filtered bus hierarchies using a tree format.

### Dependencies

Selecting the **Options** button on the right-hand side of the **Filter by name** edit box () enables this parameter.

## Selected signals

Shows the signals to be output.

### Settings

**Default:** signal1, signal2

You can change the list by using the **Up**, **Down**, and **Remove** buttons.

### Tips

- Port connectivity is maintained when the signal order is changed.
- If an output signal listed in the **Selected signals** list box is not an input to the Bus Selector block, the signal name starts with three question marks (???).

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Output as bus

Output the selected elements as a bus.

### Settings

**Default:** Off

On

Output the selected elements as a bus.

Off

Output the selected elements as standalone signals, each from an output port that is labeled with the corresponding element's name.

### Tips

- The output bus is virtual. To produce nonvirtual bus output, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to **Nonvirtual bus** and use a Simulink.Bus bus object for the **Data type** parameter. For an example, see the Signal Conversion documentation.
- If the **Selected signals** list box includes only one signal and you enable **Output as bus**, then:
  - If the selected signal is a non-bus signal, it is treated as a non-bus signal (it is not wrapped in a bus).
  - If the selected signal is a bus signal, then the output is that bus signal.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Examples

For an example of how the Bus Selector block works, see the `busdemo` model.

## Characteristics

Data types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional signals	Yes
Variable-size signals	Yes
Code generation	Yes

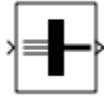

## See Also

Introduced before R2006a

## Bus to Vector

Convert virtual bus to vector

### Library

Signal Attributes

### Description

The Bus to Vector block converts a virtual bus signal to a vector signal. The input bus signal must consist of scalar, 1-D, or either row or column vectors having the same data type, signal type, and sampling mode. If the input bus contains row or column vectors, this block outputs a row or column vector, respectively; otherwise, it outputs a 1-D array.

Use the Bus to Vector block only to replace an implicit bus-to-vector conversion with an equivalent explicit conversion.

---

**Note** Simulink hides the name of a Bus to Vector block when you copy it from the Simulink library to a model.

---

### Data Type Support

The Bus to Vector block accepts virtual bus signals and nonbus signals. If the input is a nonbus signal, this block has no effect.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

This block has no user-accessible parameters.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

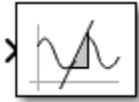

## See Also

**Introduced in R2007a**

## Check Discrete Gradient

Check that absolute value of difference between successive samples of discrete signal is less than upper bound

### Library

Model Verification

### Description

The Check Discrete Gradient block checks each signal element at its input to determine whether the absolute value of the difference between successive samples of the element is less than an upper bound. Use the block parameter dialog box to specify the value of the upper bound (1 by default). If the verification condition is true, the block does nothing. Otherwise, the block halts the simulation, by default, and displays an error in the Diagnostic Viewer.

The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box lets you enable or disable all model verification blocks, including Check Discrete Gradient blocks, in a model.

The Check Discrete Gradient block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Discrete Gradient block accepts `single`, `double`, `int8`, `int16`, and `int32` input signals of any dimensions. This block also supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Maximum gradient

Specify the upper bound on the gradient of the discrete input signal.

### Enable assertion

Clearing this check box disables the Check Discrete Gradient block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Discrete Gradient blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Discrete Gradient block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Discrete Gradient block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

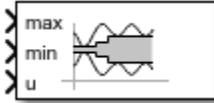

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

# Check Dynamic Gap

Check that gap of possibly varying width occurs in range of signal's amplitudes

## Library

Model Verification

## Description

The Check Dynamic Gap block checks that a gap of possibly varying width occurs in the range of a signal's amplitudes. The test signal is the signal connected to the input labeled *sig*. The inputs labeled *min* and *max* specify the lower and upper bounds of the dynamic gap, respectively. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Gap block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Dynamic Gap block accepts input signals of any dimensions and of any numeric data type that Simulink supports. All three input signals must have the same

dimension and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signals.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable assertion

Clearing this check box disables the Check Dynamic Gap block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Dynamic Gap blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Gap block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Dynamic Gap block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

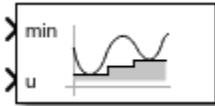

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Check Dynamic Lower Bound

Check that one signal is always less than another signal

### Library

Model Verification

### Description

The Check Dynamic Lower Bound block checks that the amplitude of a reference signal is less than the amplitude of a test signal at the current time step. The test signal is the signal connected to the input labeled *sig*. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Lower Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

### Data Type Support

The Check Dynamic Lower Bound block accepts input signals of any numeric data type that Simulink supports. The test and the reference signals must have the same

dimensions and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable assertion

Clearing this check box disables the Check Dynamic Lower Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks, including Check Dynamic Lower Bound blocks, in a model regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Lower Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Dynamic Lower Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

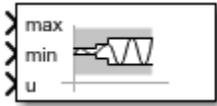

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

controlengineers.ir

## Check Dynamic Range

Check that signal falls inside range of amplitudes that varies from time step to time step

### Library

Model Verification

### Description

The Check Dynamic Range block checks that a test signal falls inside a range of amplitudes at each time step. The width of the range can vary from time step to time step. The input labeled *sig* is the test signal. The inputs labeled *min* and *max* are the lower and upper bounds of the valid range at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Range block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

### Data Type Support

The Check Dynamic Range block accepts input signals of any dimensions and of any numeric data type that Simulink supports. All three input signals must have the same

dimension and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signals.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable assertion

Clearing this check box disables the Check Dynamic Range block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Dynamic Range blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Range block to halt the simulation when the block's output is zero and the Simulink software display an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Dynamic Range block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

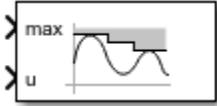

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Check Dynamic Upper Bound

Check that one signal is always greater than another signal

## Library

Model Verification

## Description

The Check Dynamic Upper Bound block checks that the amplitude of a reference signal is greater than the amplitude of a test signal at the current time step. The test signal is the signal connected to the input labeled *sig*. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Upper Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error-checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Dynamic Upper Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports. The test and the reference signals must

have the same dimensions and data type. If the inputs are nonscalar, the block compares each element of the input test signal to the corresponding elements of the reference signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable assertion

Clearing this check box disables the Check Dynamic Upper Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks, including Check Dynamic Upper Bound blocks, in a model regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Upper Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Dynamic Upper Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that

represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

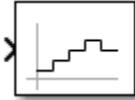

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

## Check Input Resolution

Check that input signal has specified resolution

### Library

Model Verification

### Description

The Check Input Resolution block checks whether the input signal has a specified scalar or vector resolution (see Resolution). If the resolution is a scalar, the input signal must be a multiple of the resolution within a  $10e-3$  tolerance. If the resolution is a vector, the input signal must equal an element of the resolution vector. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Input Resolution block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Input Resolution block accepts input signals of data type `double` and of any dimension. If the input signal is nonscalar, the block checks the resolution of each element of the input test signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Resolution

Specify the resolution that the input signal must have.

### Enable assertion

Clearing this check box disables the Check Input Resolution block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Input Resolution blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Input Resolution block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Input Resolution block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `boolean` if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

# Check Static Gap

Check that gap exists in signal's range of amplitudes

## Library

Model Verification

## Description

The Check Static Gap block checks that each element of the input signal is less than (or optionally equal to) a static lower bound or greater than (or optionally equal to) a static upper bound at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Gap block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Static Gap block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Upper bound

Specify the upper bound of the gap in the input signal's range of amplitudes.

### Inclusive upper bound

Selecting this check box specifies that the gap includes the upper bound.

### Lower bound

Specify the lower bound of the gap in the input signal's range of amplitudes.

### Inclusive lower bound

Selecting this check box specifies that the gap includes the lower bound.

### Enable assertion

Clearing this check box disables the Check Static Gap block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Gap blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Static Gap block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Static Gap block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **Optimization** pane of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion condition on the icon. The **text** option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

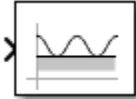

### Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Check Static Lower Bound

Check that signal is greater than (or optionally equal to) static lower bound

### Library

Model Verification

### Description

The Check Static Lower Bound block checks that each element of the input signal is greater than (or optionally equal to) a specified lower bound at the current time step. Use the block parameter dialog box to specify the value of the lower bound and whether the lower bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Lower Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

### Data Type Support

The Check Static Lower Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Lower bound

Specify the lower bound on the range of amplitudes that the input signal can have.

### Inclusive boundary

Selecting this check box makes the range of valid input amplitudes include the lower bound.

### Enable assertion

Clearing this check box disables the Check Static Lower Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Lower Bound blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Static Lower Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Static Lower Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion

condition on the icon. The text option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

# Check Static Range

Check that signal falls inside fixed range of amplitudes

## Library

Model Verification

## Description

The Check Static Range block checks that each element of the input signal falls inside the same range of amplitudes at each time step. Use the block parameter dialog box to specify the upper and lower bounds of the valid amplitude range and whether the range includes the bounds. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Range block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Static Range block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Upper bound

Specify the upper bound of the range of valid input signal amplitudes.

### Inclusive upper bound

Selecting this check box specifies that the valid signal range includes the upper bound.

### Lower bound

Specify the lower bound of the range of valid input signal amplitudes.

### Inclusive lower bound

Selecting this check box specifies that the valid signal range includes the lower bound.

### Enable assertion

Clearing this check box disables the Check Static Range block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Range blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Static Range block to halt the simulation when the block's output is zero and the Simulink software display an error.

Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Static Range block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab

of the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

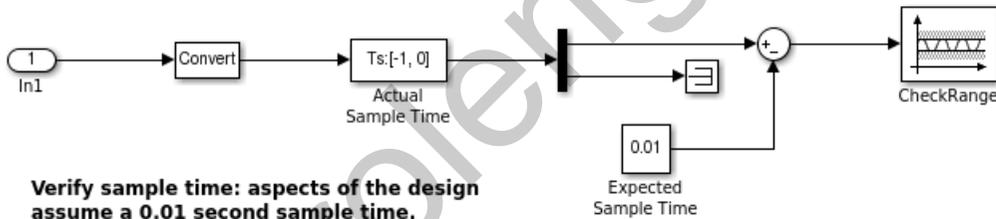

### Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Examples

The `sldemo_fuelsys` model shows how you can use the Check Static Range block to verify that the sample time is consistent throughout the model.

The Check Static Range block appears in the `sldemo_fuelsys/fuel_rate_control/validate_sample_time` subsystem.

## Characteristics

# Check Static Upper Bound

Check that signal is less than (or optionally equal to) static upper bound

## Library

Model Verification

## Description

The Check Static Upper Bound block checks that each element of the input signal is less than (or optionally equal to) a specified upper bound at the current time step. Use the block parameter dialog box to specify the value of the upper bound and whether the bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Upper Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

---

**Note:** For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

---

## Data Type Support

The Check Static Upper Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Upper bound

Specify the upper bound on the range of amplitudes that the input signal can have.

### Inclusive boundary

Selecting this check box makes the range of valid input amplitudes include the upper bound.

### Enable assertion

Clearing this check box disables the Check Static Upper Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting on the **All Parameters** tab in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Upper Bound blocks, regardless of the setting of this option.

### Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

### Stop simulation when assertion fails

Selecting this check box causes the Check Static Upper Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

### Output assertion signal

Selecting this check box causes the Check Static Upper Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is **Boolean** if you have selected the **Implement logic signals as Boolean data** check box on the **All Parameters** tab of the Configuration Parameters dialog box. Otherwise the data type of the output signal is **double**.

### Select icon type

Specify the type of icon used to display this block in a block diagram: either **graphic** or **text**. The **graphic** option displays a graphical representation of the assertion

condition on the icon. The text option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

# Chirp Signal

Generate sine wave with increasing frequency

## Library

Sources

## Description

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. You can use this block for spectral analysis of nonlinear systems. The block generates a scalar or vector output.

The parameters, **Initial frequency**, **Target time**, and **Frequency at target time**, determine the block's output. You can specify any or all of these variables as scalars or arrays. All the parameters specified as arrays must have the same dimensions. The block expands scalar parameters to have the same dimensions as the array parameters. The block output has the same dimensions as the parameters unless you select the **Interpret vector parameters as 1-D** check box. If you select this check box and the parameters are row or column vectors, the block outputs a vector (1-D array) signal.

The following limitations apply to the Chirp Signal block:

- The start time of the simulation must be 0. To confirm this value, go to the **Solver** pane in the Configuration Parameters dialog box and view the **Start time** field.
- Suppose that you use a Chirp Signal block in an enabled subsystem. Whenever the subsystem is enabled, the block output matches what would appear if the subsystem were enabled throughout the simulation.

## Data Type Support

The Chirp Signal block outputs a real-valued signal of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial frequency

The initial frequency of the signal, specified as a scalar or matrix value. The default is 0.1 Hz.

### Target time

The time at which the frequency reaches the **Frequency at target time** parameter value, a scalar or matrix value. The frequency continues to change at the same rate after this time. The default is 100 seconds.

### Frequency at target time

The frequency of the signal at the target time, a scalar or matrix value. The default is 1 Hz.

### Interpret vector parameters as 1-D

If selected, column or row matrix values for the **Initial frequency**, **Target time**, and **Frequency at target time** parameters result in a vector output whose elements are the elements of the row or column. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

## Characteristics

Data Types	Double
Sample Time	Continuous

# Clock

Display and provide simulation time

## Library

Sources

## Description

The Clock block outputs the current simulation time at each simulation step. This block is useful for other blocks that need the simulation time.

When you need the current time within a discrete system, use the **Digital Clock** block.

## Data Type Support

The Clock block outputs a real-valued signal of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Display time

Select this check box to display the current simulation time inside the Clock block icon.

### Decimation

Specify a positive integer for the interval at which Simulink updates the Clock icon when you select **Display time**.

Suppose that the decimation is 1000. For a fixed integration step of 1 millisecond, the Clock icon updates at 1 second, 2 seconds, and so on.

## Examples

The following Simulink examples show how to use the Clock block:

- sldemo\_tonegen\_fixpt
- penddemo

## Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

# Combinatorial Logic

Implement truth table

## Library

Logic and Bit Operations

## Description

The Combinatorial Logic block implements a standard truth table for modeling programmable logic arrays (PLAs), logic circuits, decision tables, and other Boolean expressions. You can use this block in conjunction with Memory blocks to implement finite-state machines or flip-flops.

You specify a matrix that defines all possible block outputs as the **Truth table** parameter. Each row of the matrix contains the output for a different combination of input elements. You must specify outputs for every combination of inputs. The number of columns is the number of block outputs.

The relationship between the number of inputs and the number of rows is:

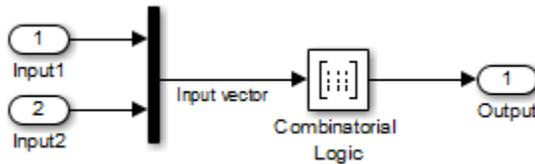

$$\text{number of rows} = 2^{\text{(number of inputs)}}$$

Simulink returns a row of the matrix by computing the row's index from the input vector elements. Simulink computes the index by building a binary number where input vector elements having zero values are 0 and elements having nonzero values are 1, then adding 1 to the result. For an input vector,  $u$ , of  $m$  elements:

$$\text{row index} = 1 + u(m) \cdot 2^0 + u(m-1) \cdot 2^1 + \dots + u(1) \cdot 2^{m-1}$$

## Two-Input AND Logic

This example builds a two-input AND function, which returns 1 when both input elements are 1, and 0 otherwise. To implement this function, specify the **Truth table** parameter value as [0; 0; 0; 1]. The portion of the model that provides the inputs to and the output from the Combinatorial Logic block might look like this:

The following table indicates the combination of inputs that generate each output. The input signal labeled “Input 1” corresponds to the column in the table labeled Input 1. Similarly, the input signal “Input 2” corresponds to the column with the same name. The combination of these values determines the row of the Output column of the table that is passed as block output.

For example, if the input vector is [1 0], the input references the third row:

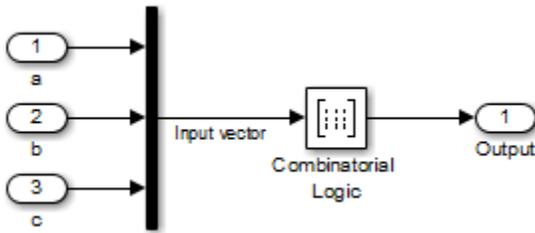

$$(2^{1*1} + 1)$$

The output value is 0.

Row	Input 1	Input 2	Output
1	0	0	0
2	0	1	0
3	1	0	0
4	1	1	1

## Circuit Logic

This sample circuit has three inputs: the two bits (**a** and **b**) to be summed and a carry-in bit (**c**). It has two outputs: the carry-out bit (**c'**) and the sum bit (**s**).

The truth table and corresponding outputs for each combination of input values for this circuit appear in the following table.

Inputs			Outputs	
a	b	c	c'	s
0	0	0	0	0
0	0	1	0	1
0	1	0	0	1
0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

To implement this adder with the Combinatorial Logic block, you enter the 8-by-2 matrix formed by columns **c'** and **s** as the **Truth table** parameter.

You can also implement sequential circuits (that is, circuits with states) with the Combinatorial Logic block by including an additional input for the state of the block and feeding the output of the block back into this state input.

## Data Type Support

The type of signals accepted by a Combinatorial Logic block depends on whether you selected the Boolean logic signals option (see “Implement logic signals as Boolean data

(vs. double”). If this option is enabled, the block accepts real signals of type **Boolean** or **double**. The **Truth table** parameter can have Boolean values (0 or 1) of any data type, including fixed-point data types. If the table contains non-Boolean values, the data type of the table must be **double**.

The type of the output is the same as that of the input except that the block outputs **double** if the input is **Boolean** and the truth table contains non-Boolean values.

If Boolean compatibility mode is disabled, the Combinatorial Logic block accepts only signals of type **Boolean**. The block outputs **double** if the truth table contains non-Boolean values of type **double**. Otherwise, the output is **Boolean**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Truth table

Specify the matrix of outputs. Each column corresponds to an element of the output vector and each row corresponds to a row of the truth table.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

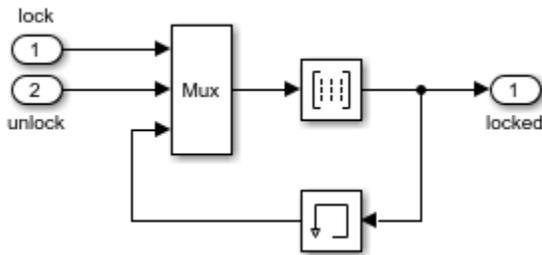

---

## Examples

### Usage with the Memory Block to Implement a Finite-State Machine

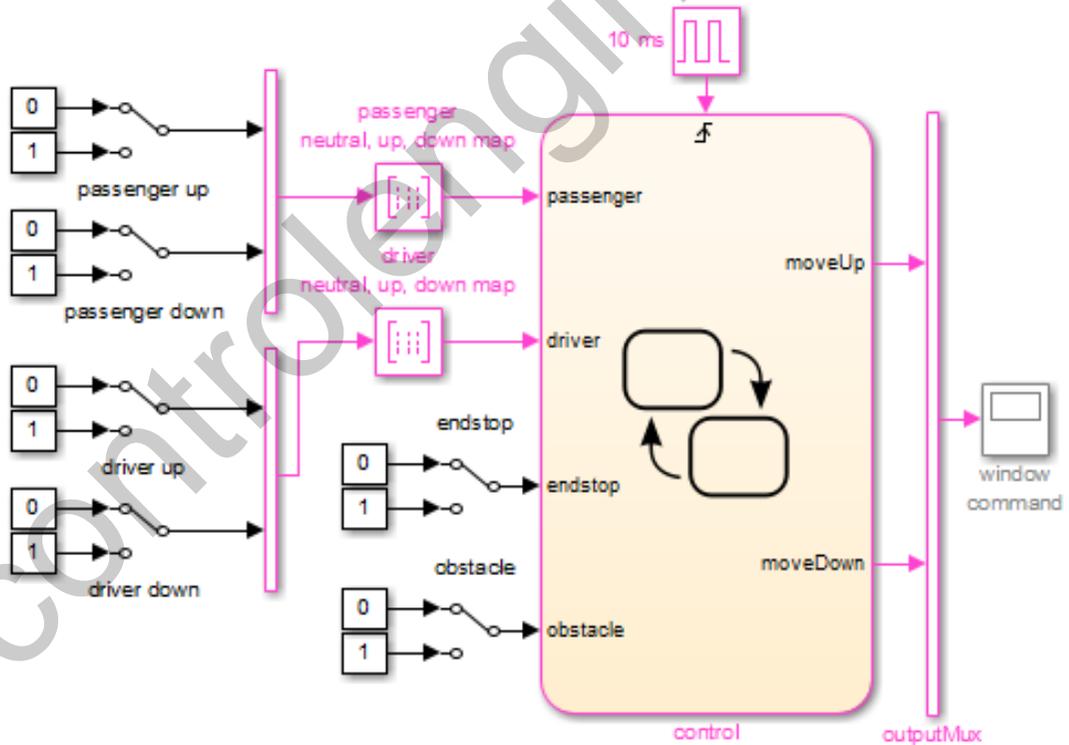

The `sldemo_clutch` model shows how you can use the Combinatorial Logic block with the Memory block to implement a finite-state machine.

The finite-state machine appears in the **Friction Mode Logic/Lockup FSM** subsystem.

### Usage with a Stateflow Chart to Implement a Finite-State Machine

The powerwindow model shows how you can use two Combinatorial Logic blocks as inputs to a Stateflow chart to implement a finite-state machine.

## Characteristics

Data Types	Double   Boolean
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Compare To Constant

Determine how signal compares to specified constant

### Library

Logic and Bit Operations

### Description

The Compare To Constant block compares an input signal to a constant. Specify the constant in the **Constant value** parameter. Specify how the input is compared to the constant value with the **Operator** parameter. The **Operator** parameter can have the following values:

- == — Determine whether the input is equal to the specified constant.
- ~= — Determine whether the input is not equal to the specified constant.
- < — Determine whether the input is less than the specified constant.
- <= — Determine whether the input is less than or equal to the specified constant.
- > — Determine whether the input is greater than the specified constant.
- >= — Determine whether the input is greater than or equal to the specified constant.

The output is 0 if the comparison is false, and 1 if it is true.

### Data Type Support

The Compare To Constant block accepts inputs of any data type that Simulink supports, including fixed-point and enumerated data types. The block first converts its **Constant**

**value** parameter to the input data type, and then performs the specified operation. The block output is `uint8` or `boolean` as specified by the **Output data type** parameter.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Operator

Specify how the input is compared to the constant value, as discussed in Description.

### Constant value

Specify the constant value to which the input is compared.

### Output data type

Specify the data type of the output, `boolean` or `uint8`.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

Compare To Zero

Introduced before R2006a

controlengineers.ir

## Compare To Zero

Determine how signal compares to zero

### Library

Logic and Bit Operations

### Description

The Compare To Zero block compares an input signal to zero. Specify how the input is compared to zero with the **Operator** parameter. The **Operator** parameter can have the following values:

- == — Determine whether the input is equal to zero.
- ~= — Determine whether the input is not equal to zero.
- < — Determine whether the input is less than zero.
- <= — Determine whether the input is less than or equal to zero.
- > — Determine whether the input is greater than zero.
- >= — Determine whether the input is greater than or equal to zero.

The output is 0 if the comparison is false, and 1 if it is true.

### Data Type Support

The Compare To Zero block accepts inputs of the following data types:

- Floating point
- Built-in integer

- Fixed point
- Boolean

The block output is `uint8` or `boolean`, depending on your selection for the **Output data type** parameter. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

---

**Tip:** If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to `warning` or `error`.

In this case, the block compares the input signal to the *ground value* of the input data type. For example, if you have an input signal of type `fixdt(0,8,2^0,10)`, the input data type can represent unsigned 8-bit integers from 10 to 265 due to a bias of 10. The ground value is 10, instead of 0.

---

## Parameters

### Operator

Specify how the input is compared to zero, as discussed in Description.

### Output data type

Specify the data type of the output, `boolean` or `uint8`.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes

Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

Compare To Constant

## Complex to Magnitude-Angle

Compute magnitude and/or phase angle of complex signal

### Library

Math Operations

### Description

The Complex to Magnitude-Angle block accepts a complex-valued signal of type `double` or `single`. It outputs the magnitude and/or phase angle of the input signal, depending on the setting of the **Output** parameter. The outputs are real values of the same data type as the block input. The input can be an array of complex signals, in which case the output signals are also arrays. The magnitude signal array contains the magnitudes of the corresponding complex input elements. The angle output similarly contains the angles of the input elements.

### Data Type Support

See the preceding description.

### Parameters

#### Output

Determines the output of this block. Choose from the following values: `Magnitude and angle` (outputs the input signal's magnitude and phase angle in radians), `Magnitude` (outputs the input's magnitude), `Angle` (outputs the input's phase angle in radians).

## Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

## Characteristics

Data Types	Double   Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Complex to Real-Imag

Output real and imaginary parts of complex input signal

### Library

Math Operations

### Description

The Complex to Real-Imag block accepts a complex-valued signal of any data type that Simulink supports, including fixed-point data types. It outputs the real and/or imaginary part of the input signal, depending on the setting of the **Output** parameter. The real outputs are of the same data type as the complex input. The input can be an array (vector or matrix) of complex signals, in which case the output signals are arrays of the same dimensions. The real array contains the real parts of the corresponding complex input elements. The imaginary output similarly contains the imaginary parts of the input elements.

### Data Type Support

See the preceding description. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

#### Output

Determines the output of this block. Choose from the following values: **Real** and **imag** (outputs the input signal's real and imaginary parts), **Real** (outputs the input's real part), **Imag** (outputs the input's imaginary part).

## Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

# Configurable Subsystem

Represent any block selected from user-specified library of blocks

## Library

Ports & Subsystems

## Description

The Configurable Subsystem block represents one of a set of blocks contained in a specified library of blocks. The block's context menu lets you choose which block the configurable subsystem represents.

Configurable Subsystem blocks simplify creation of models that represent families of designs. For example, suppose that you want to model an automobile that offers a choice of engines. To model such a design, you would first create a library of models of the engine types available with the car. You would then use a Configurable Subsystem block in your car model to represent the choice of engines. To model a particular variant of the basic car design, a user need only choose the engine type, using the configurable engine block's dialog.

To create a configurable subsystem in a model, you must first create a library containing a master configurable subsystem and the blocks that it represents. You can then create configurable instances of the master subsystem by dragging copies of the master subsystem from the library and dropping them into models.

You can add any type of block to a master configurable subsystem library. Simulink derives the port names for the configurable subsystem by making a unique list from the port names of all the choices. However, Simulink uses default port names for non-subsystem block choices.

Note that you cannot break library links in a configurable subsystem because Simulink uses those links to reconfigure the subsystem when you choose a new configuration. Breaking links would be useful only if you do not intend to reconfigure the subsystem. In this case, you can replace the configurable subsystem with a nonconfigurable subsystem that implements the permanent configuration.

## Creating a Master Configurable Subsystem

To create a master configurable subsystem:

- 1 Create a library of blocks representing the various configurations of the configurable subsystem.
- 2 Save the library.
- 3 Create an instance of the Configurable Subsystem block in the library.

To do this, drag a copy of the Configurable Subsystem block from the Simulink Ports & Subsystems library into the library you created in the previous step.

- 4 Display the Configurable Subsystem block dialog by double-clicking it. The dialog displays a list of the other blocks in the library.
- 5 Under **List of block choices** in the dialog box, select the blocks that represent the various configurations of the configurable subsystems you are creating.
- 6 Click the **OK** button to apply the changes and close the dialog box.
- 7 Select **Block Choice** from the Configurable Subsystem block's context menu.

The context menu displays a submenu listing the blocks that the subsystem can represent.

- 8 Select the block that you want the subsystem to represent by default.
- 9 Save the library.

---

**Note:** If you add or remove blocks from a library, you must recreate any Configurable Subsystem blocks that use the library.

---

If you modify a library block that is the default block choice for a configurable subsystem, the change does not immediately propagate to the configurable subsystem. To propagate this change, do one of the following:

- Change the default block choice to another block in the subsystem, then change the default block choice back to the original block.

- Recreate the configurable subsystem block, including the selection of the updated block as the default block choice.

If a configurable subsystem in your model contains a broken link to a library block, editing the link and saving the model does not fix the broken link the next time you open the model. To fix a broken library link in your configurable subsystem, use one of the following approaches.

- Convert the configurable subsystem to a variant subsystem. Right-click the configurable subsystem, and select **Subsystem and Model Reference > Convert Subsystem to > Variant Subsystem**.
- Remove the library block from the master configurable subsystem library, add the library block back to the master configurable subsystem library, and then resave the master configurable subsystem library.

## Creating an Instance of a Configurable Subsystem

To create an instance of a configurable subsystem in a model:

- 1 Open the library containing the master configurable subsystem.
- 2 Drag a copy of the master into the model.
- 3 Select **Block Choice** from the copy's context menu.
- 4 Select the block that you want the configurable subsystem to represent.

The instance of the configurable system displays the icon and parameter dialog box of the block that it represents.

## Setting Instance Block Parameters

As with other blocks, you can use the parameter dialog box of a configurable subsystem instance to set the instance's parameters interactively and the `set_param` command to set the parameters from the MATLAB command line or in a MATLAB file. If you use `set_param`, you must specify the full path name of the configurable subsystem's current block choice as the first argument of `set_param`, for example:

```
curr_choice = get_param('mymod/myconfigsys', 'BlockChoice');
curr_choice = ['mymod/myconfigsys/' curr_choice];
set_param(curr_choice, 'MaskValues', ...);
```

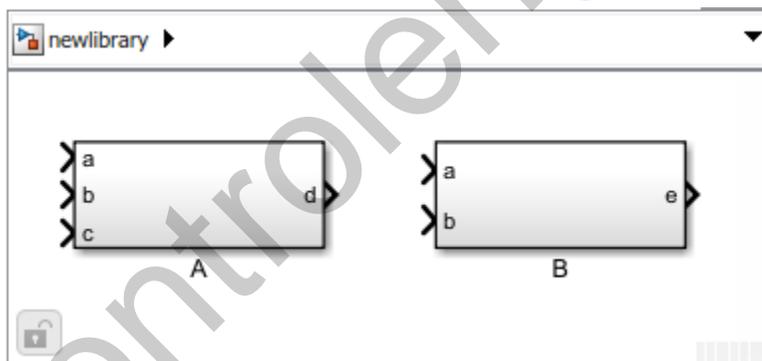

## Mapping I/O Ports

A configurable subsystem displays a set of input and output ports corresponding to input and output ports in the selected library. Simulink uses the following rules to map library ports to Configurable Subsystem block ports:

- Map each uniquely named input/output port in the library to a separate input/output port of the same name on the Configurable Subsystem block.
- Map all identically named input/output ports in the library to the same input/output ports on the Configurable Subsystem block.
- Terminate any input/output port not used by the currently selected library block with a Terminator/Ground block.

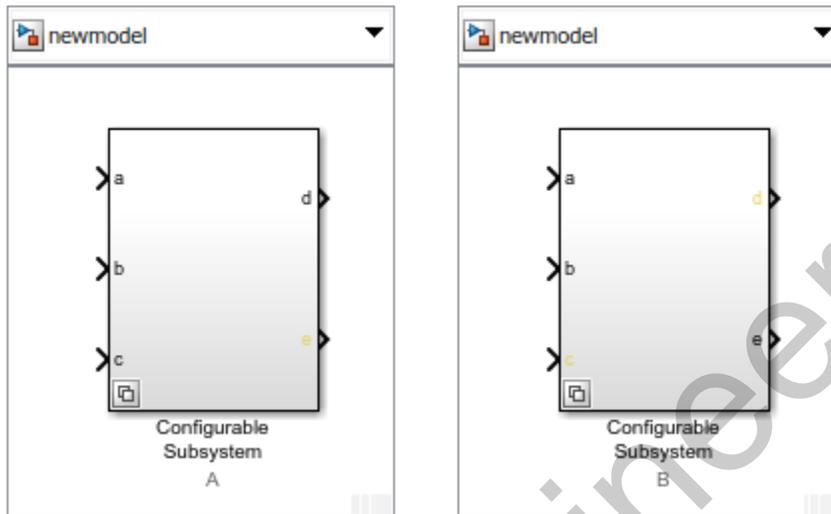

This mapping allows a user to change the library block represented by a Configurable Subsystem block without having to rewire connections to the Configurable Subsystem block.

For example, suppose that a library contains two blocks A and B and that block A has input ports labeled a, b, and c and an output port labeled d and that block B has input ports labeled a and b and an output port labeled e.

A Configurable Subsystem block based on this library would have three input ports labeled a, b, and c, respectively, and two output ports labeled d and e.

In this example, port a on the Configurable Subsystem block connects to port a of the selected library block no matter which block is selected. On the other hand, port c on the Configurable Subsystem block functions only if library block A is selected. Otherwise, it simply terminates.

**Note:** A Configurable Subsystem block does not provide ports that correspond to non-I/O ports, such as the trigger and enable ports on triggered and enabled subsystems. Thus, you cannot use a Configurable Subsystem block directly to represent blocks that have such ports. You can do so indirectly, however, by wrapping such blocks in subsystem blocks that have input or output ports connected to the non-I/O ports.

## Convert to Variant Subsystem

Right-click a configurable subsystem and select **Subsystems and Model Reference > Convert Subsystem To > Variant Subsystem**.

During conversion, Simulink performs the following operations:

- Replaces the Subsystem block with a Variant Subsystem block, preserving ports and connections.
- Adds the original subsystem as a variant choice in the Variant Subsystem block.
- Overrides the Variant Subsystem block to use the subsystem that was originally the active choice.
- Preserves links to libraries. For linked subsystems, Simulink adds the linked subsystem as a variant choice.

Simulink also preserves the subsystem block masks, and it copies the masks to the variant choice.

See **Variant Subsystem** for more information on variant choices.

## Data Type Support

The Configurable Subsystem block accepts and outputs signals of the same types that are accepted or output by the block that it currently represents. The data types can be any that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### List of block choices

Select the blocks you want to include as members of the configurable subsystem. You can include user-defined subsystems as blocks.

### Port names

Lists of input and output ports of member blocks. In the case of multiports, you can rearrange selected port positions by clicking the **Up** and **Down** buttons.

## Characteristics

A Configurable Subsystem block has the characteristics of the block that it currently represents. Double-clicking the block opens the dialog box for the block that it currently represents.

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

Introduced before R2006a

controlengineers.ir

## Constant

Generate constant value

## Library

Sources

## Description

The Constant block generates a real or complex constant value.

The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** parameter. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

## Data Type Support

By default, the Constant block outputs a signal whose data type and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types. The **Enumerated Constant** block can be more convenient than the Constant block for outputting a constant enumerated value. You can also use a bus object as the

output data type, which can help to simplify a model (see “Bus Support” on page 1-203 for details).

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

---

For more information about data type support, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Constant value

Specify the constant value output of the block.

#### Settings

**Default:** 1

**Minimum:** value from the **Output minimum** parameter

**Maximum:** value from the **Output maximum** parameter

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify either:
  - A full MATLAB structure corresponding to the bus object
  - 0 to indicate a structure corresponding to the ground value of the bus object

For details, see “Bus Support” on page 1-203.

- For non-bus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using round toward nearest and saturation.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Interpret vector parameters as 1-D

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

### Settings

**Default:** On

On

Outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1 - by - N or N - by - 1.

Off

Does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

### Settings

**Default:** inf

This setting indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” in the online documentation for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see Simulink.BusElement.

---

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see Simulink.BusElement.

---

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Output data type

Specify the output data type.

## Settings

**Default:** Inherit: Inherit from 'Constant value'

Inherit: Inherit from 'Constant value'

Use data type of **Constant value**.

Inherit: Inherit via back propagation

Use data type of the driving block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

boolean

Output data type is boolean.

fixdt(1,16)

Output data type is fixed point fixdt(1,16).

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: <class name>

Use an enumerated data type, for example, Enum: `BasicColors`.

Bus: <object name>

Data type is a bus object.

<data type expression>

Data type is data type object, for example `Simulink.NumericType`.

Do not specify a bus object as the expression.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Control Signal Data Types” for more information.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit from 'Constant value' (default)
- Inherit via back propagation

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus.

If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Bus Support

### Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. If you use a bus object as the data type, set **Constant value** to 0 or a MATLAB structure that matches the bus object.

### Using Structures for the Constant Value

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

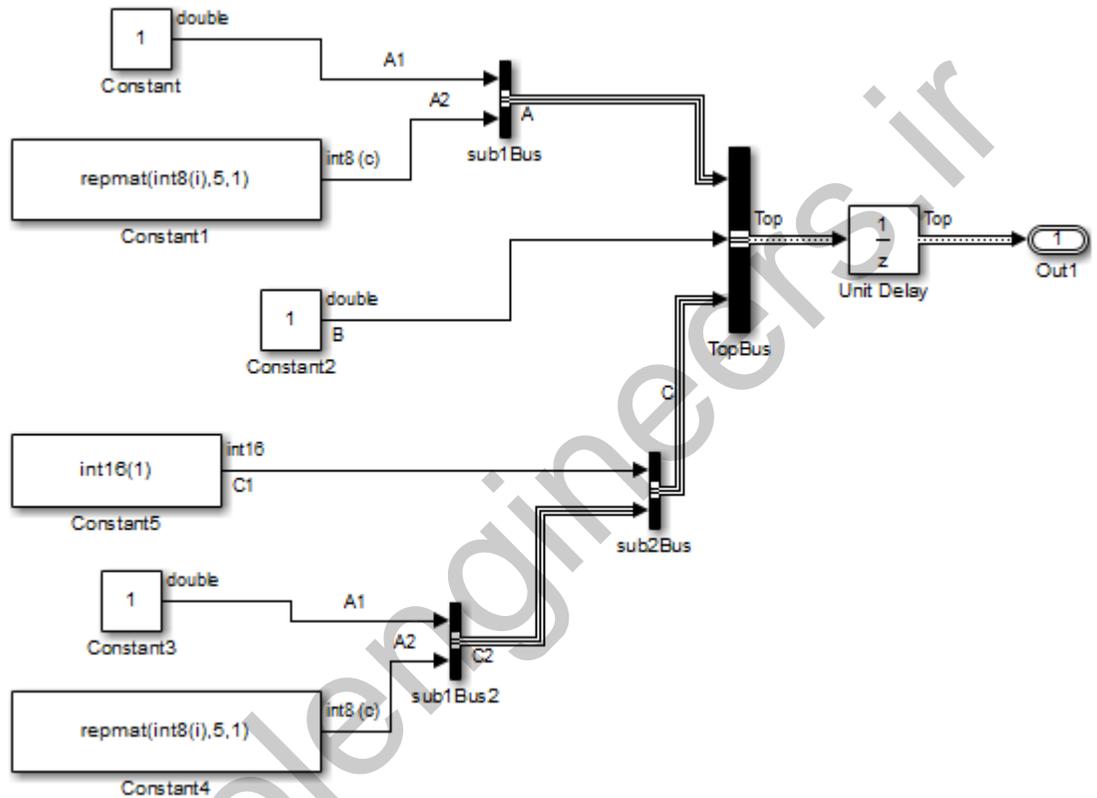

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as `37`. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields”.

## Example of Using a Bus Object for a Constant Block

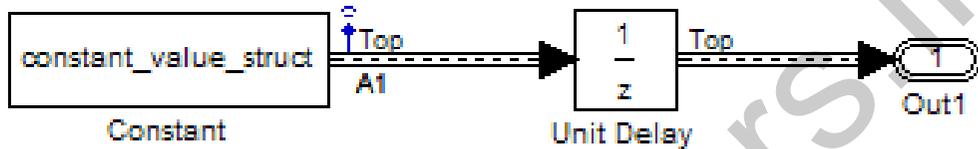

The following example illustrates how using a bus object as an output data type for a Constant block can help to simplify a model.

- 1 Open the `ex_busic` model and update it.

This model uses six Constant blocks. For details about the model, see “Examples of Partial Structures”.

- Open the `ex_constantbus` model and update it. This model uses one Constant block that replaces the six Constant blocks in the `ex_busic` model.

- 3 Simulate the `ex_constantbus` model. To verify that the output from the Constant block reflects the values from `constant_value_struct`, perform the next two steps.
- 4 At the MATLAB command line, examine the `constant_value_struct` structure that the Constant block uses for its **Constant value** parameter.

```
constant_value_struct
```

```
constant_value_struct =
```

```
A: [1x1 struct]  
B: 5  
C: [1x1 struct]
```

- 5 Examine the logged data in the `logouts` variable, focusing on the B element of the A1 bus signal. The `constant_value_struct` structure sets the B element to 5.

```
logouts.get('A1').Values.B.Data
```

## Group Constant Signals into an Array of Buses

You can use a Constant block to compactly represent multiple constant-valued signals as an array of buses. You can use this technique to reduce the number of signal lines in a model and the number of variables that the model uses, especially when the model repeats an algorithm with different parameter values.

To generate a constant-valued array of bus signals, use an array of MATLAB structures in a Constant block. The block output is an array of buses, and each field in the array of structures provides the simulation value for the corresponding signal element.

You can also use an array of structures to specify the **Value** property of a `Simulink.Parameter` object, and use the parameter object in a Constant block.

- 1 Open the example model `ex_constantbus_array`.

The variables `ParamBus` and `const_param_struct` appear in the base workspace. The variable `const_param_struct` contains a structure whose field names match the elements of the bus type that `ParamBus` defines.

- 2 Update the diagram to view the signal line widths.

The output of the Constant block is a single scalar bus of type `ParamBus`. The structure variable `const_param_struct` specifies the constant value in the block.

- 3 At the command prompt, create an array of two structures by copying the structure `const_param_struct`. Customize the field values by indexing into the individual structures in the array.

```
const_struct_array = ...
    [const_param_struct const_param_struct];
```

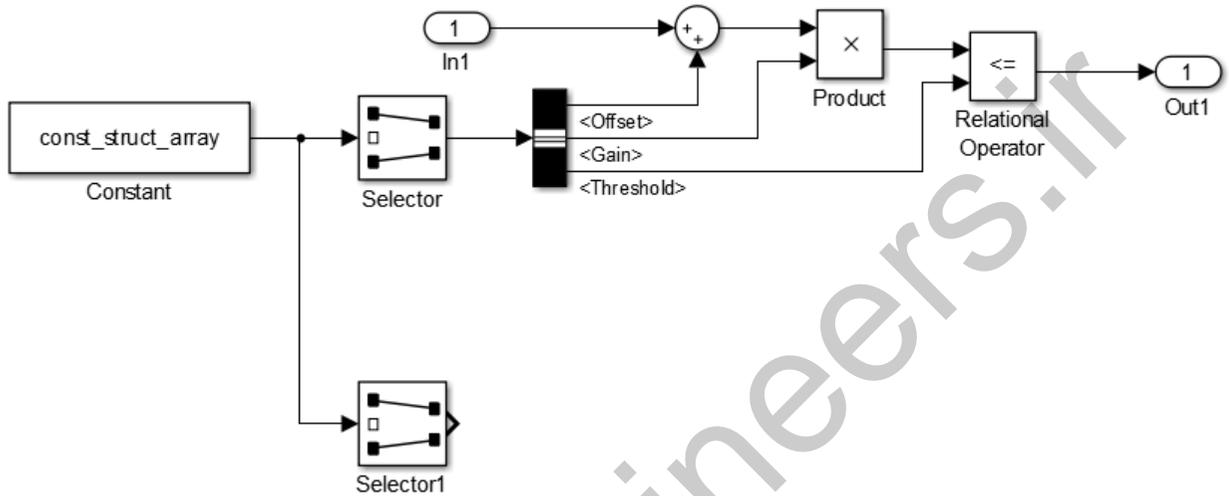

```
const_struct_array(2).Offset = 158;
const_struct_array(2).Gain = 3.83;
const_struct_array(2).Threshold = 1039.77
```

```
const_struct_array =
1x2 struct array with fields:
```

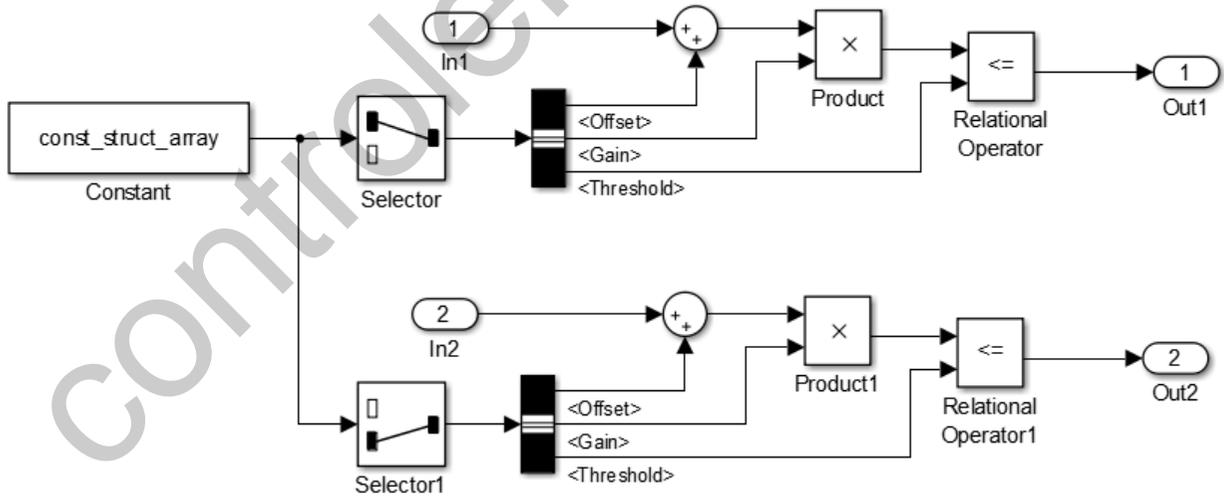

```
    Offset
    Gain
    Threshold
```

- 4 In the Constant block dialog box, set **Constant value** to `const_struct_array`.
- 5 Add two Selector blocks to the model, and connect the Constant block as shown.

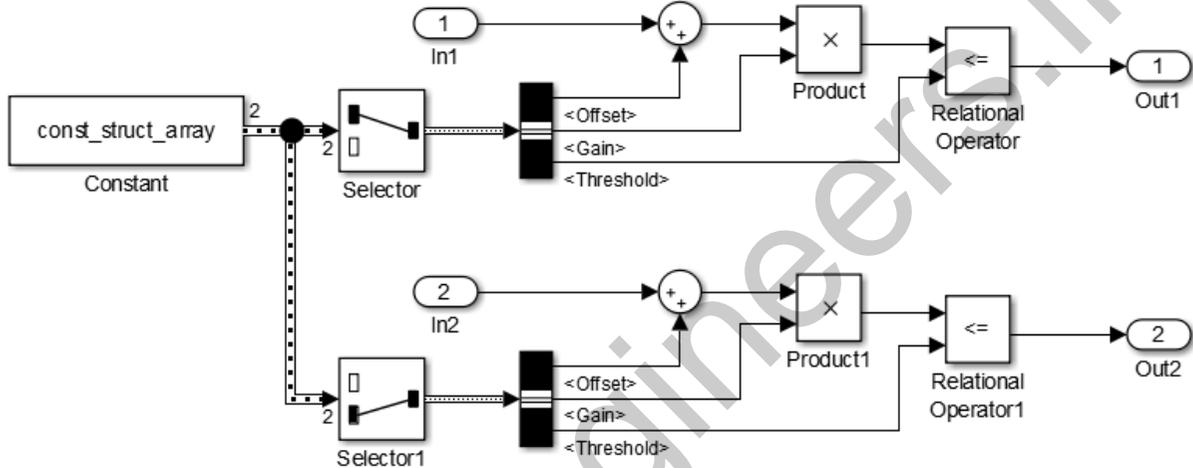

1 Blocks – Alphabetical List

- 6 In the Selector block dialog box, set **Index** to 1 and **Input port size** to 2.
- 7 In the Selector1 block dialog box, set **Index** to 2 and **Input port size** to 2.
- 8 Copy the block algorithm in the model, and connect the blocks as shown.

- 9 Update the diagram. The signal line width and style indicate that the output of the Constant block is an array of buses. The Selector blocks each extract one of the buses in the array.

Each copy of the algorithm uses the constant values provided by the corresponding structure in the variable `const_struct_array`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`. You can also use this technique to create an array of structures if you do not have a scalar structure that you can copy.

## Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**. For more information, see “Underspecified initialization detection”.

## Examples

The following Simulink examples show how to use the Constant block:

- sldemo\_auto\_climatecontrol
- sldemo\_boiler
- sldemo\_bounce

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	N/A
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Cosine HDL Optimized

Implement fixed-point cosine wave optimized for HDL code generation

### Library

HDL Coder™ / Lookup Tables

### Description

The Cosine HDL Optimized block implements a fixed-point cosine wave by using a lookup table method that exploits quarter-wave symmetry.

You define the number of lookup table points in the **Number of data points** parameter. The block implementation is most efficient for HDL code generation when you specify the lookup table data points to be  $(2^n)$ , where  $n$  is an integer. For information about the behavior of this block in HDL Coder, see Cosine HDL Optimized.

Depending on your selection of the **Output formula** parameter, the blocks can output these functions of the input signal:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$  and  $\cos(2\pi u)$

Use the **Table data type** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

## Data Type Support

The Cosine HDL Optimized block accepts signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Output formula

Select the signal(s) to output.

### Number of data points

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be  $(2^n)$ , where  $n$  is an integer.

### Table data type

Specify the table data type. You can specify an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

### Show data type assistant

Select the mode of data type specification. If you select **Expression**, enter an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

If you select **Fixed point**, you can use the options in the **Data Type Assistant** to specify the fixed-point data type. In the **Fixed point** mode, you can choose binary point scaling, and specify the signedness, word length, fraction length, and the data type override setting.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Coulomb and Viscous Friction

Model discontinuity at zero, with linear gain elsewhere

### Library

Discontinuities

### Description

The Coulomb and Viscous Friction block models Coulomb (static) and viscous (dynamic) friction. The block models a discontinuity at zero and a linear gain otherwise.

The block output matches the MATLAB result for:

$$y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$$

where  $y$  is the output,  $x$  is the input, **Gain** is the signal gain for nonzero input values, and **Offset** is the Coulomb friction.

The block accepts one input and generates one output. The input can be a scalar, vector, or matrix with real and complex elements.

- For a scalar input, **Gain** and **Offset** can have dimensions that differ from the input. The output is a scalar, vector, or matrix depending on the dimensions of **Gain** and **Offset**.
- For a vector or matrix input, **Gain** and **Offset** must be scalar or have the same dimensions as the input. The output is a vector or matrix of the same dimensions as the input.

### Data Type Support

The Coulomb and Viscous Friction block supports real inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point

The block supports complex inputs only for floating-point data types, **double** and **single**. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Coulomb friction value

Specify the offset that applies to all input values.

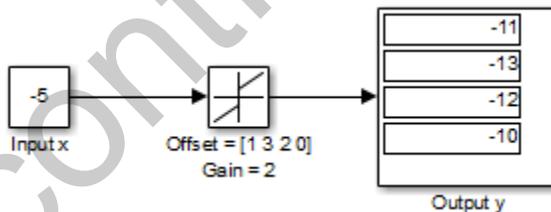

### Coefficient of viscous friction

Specify the signal gain for nonzero input values.

## Examples

### Scalar Input

Suppose that you have the following model:

In this model, the block input  $x$  (-5) and **Gain** (2) are scalar values, but **Offset** is the vector [1 3 2 0]. Therefore, the block uses element-wise scalar expansion to compute the output.

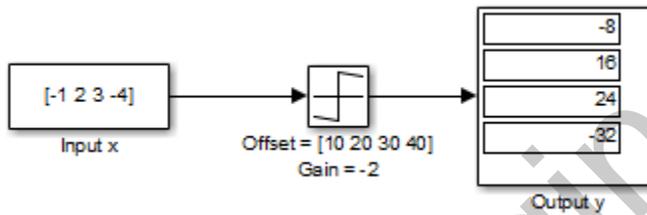

For example, for the first offset, 1, the output is calculated using the formula  $y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$  as follows:

$$y = - * (2 * 5) + 1$$

$$y = -11$$

## Vector Input

Suppose that you have the following model:

In this model, vector dimensions for block input  $x$  and  $\text{Offset}$  are the same.

## Matrix Input

Suppose that you have the following model:

In this model, matrix dimensions for block input  $x$  and  $\text{Offset}$  are the same.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

## Counter Free-Running

Count up and overflow back to zero after reaching maximum value for specified number of bits

### Library

Sources

### Description

The Counter Free-Running block counts up until reaching the maximum value,  $2^{Nbits} - 1$ , where  $Nbits$  is the number of bits. Then the counter overflows to zero and begins counting up again.

After overflow, the counter always initializes to zero. However, if you select the global doubles override, the Counter Free-Running block does not wrap back to zero.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

### Data Type Support

The Counter Free-Running block outputs an unsigned integer.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of Bits

Specify the number of bits.

When you use...	Such as...	The block counts up to...	Which is...
A positive integer	8	$2^8 - 1$	255
An unsigned integer expression	uint8(8)	uint8( $2^{\text{uint8}(8)} - 1$ )	254

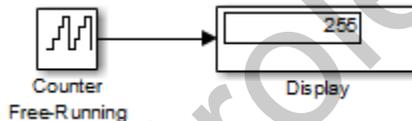

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the Simulink documentation.

## Examples

### Bit Specification Using a Positive Integer

Suppose that you have the following model:

The block parameters are:

Parameter	Setting
Number of Bits	8
Sample time	-1

The solver options for the model are:

Parameter	Setting
Stop time	255

Parameter	Setting
Type	Fixed-step
Solver	discrete (no continuous states)
Fixed-step size	1

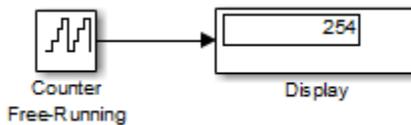

At  $t = 255$ , the counter reaches the maximum value:

$$2^8 - 1$$

If you change the stop time of the simulation to 256, the counter wraps to zero.

## Bit Specification Using an Unsigned Integer Expression

Suppose that you have the following model:

The block parameters are:

Parameter	Setting
Number of Bits	uint8(8)
Sample time	-1

The solver options for the model are:

Parameter	Setting
Stop time	254
Type	Fixed-step
Solver	discrete (no continuous states)
Fixed-step size	1

At  $t = 254$ , the counter reaches the maximum value:

$$\text{uint8}(2^{\text{uint8}(8)} - 1)$$

If you change the stop time of the simulation to 255, the counter wraps to zero.

## Characteristics

Data Types	Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Counter Limited MATLAB Function

Introduced before R2006a

Controlengineers.ir

## Counter Limited

Count up and wrap back to zero after outputting specified upper limit

## Library

Sources

## Description

The Counter Limited block counts up until the specified upper limit is reached. Then the counter wraps back to zero, and restarts counting up. The counter always initializes to zero.

You can specify the upper limit with the **Upper limit** parameter.

You can specify the sample time with the **Sample time** parameter. A **Sample time** of -1 means that the sample time is inherited.

The output is an unsigned integer of 8, 16, or 32 bits, with the smallest number of bits needed to represent the upper limit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

## Data Type Support

The Counter Limited block outputs an unsigned integer.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Upper limit

Specify the upper limit.

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the Simulink documentation.

## Examples

The following Simulink examples show how to use the Counter Limited block:

- `sldemo_tonegen_fixpt`

## Characteristics

Data Types	Boolean   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

# Dashboard Scope

Trace signals during simulation

## Library

Dashboard

## Description

The Dashboard Scope block displays connected signals during simulation on a scope display.

To view data from signals, double-click the Dashboard Scope block to open the dialog box. Select signals in the model. The signals appear in the **Connection** table. Select the check box next to each signal you want to display in the scope. Click **Apply** to connect the signals.

You can also add data cursors to the Dashboard Scope to inspect signal data. To add a data cursor, select the Dashboard Scope block and right-click. Select **Data Cursors > One** from the menu.

To change zoom and pan modes, select the Dashboard Scope block, right-click, and select the zoom or pan mode you want.

## Limitations

The Dashboard Scope block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to the Dashboard Scope block, signal data does not stream to the block. To view signal data again, double-click the Dashboard Scope block and reconnect the signal.

External mode simulation does not support the Dashboard Scope block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Data Type Support

The Dashboard Scope block accepts real (not complex) signals of any data type that Simulink supports, including enumerated data types.

For more information on data types in Simulink, see “Data Types Supported by Simulink”.

## Parameters

### Connection

Select signals to connect and display.

To view data from signals, double-click the Dashboard Scope block to open the dialog box. Select signals in the model. The signals appear in the **Connection** table. Select the check box next to each signal you want to display in the scope. Click **Apply** to connect the signals.

### Settings

The table has a row for the signals connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### T-Axis Limits

Horizontal axis time span.

### Settings

**Default:** auto

Specify this number as a finite, real, double, scalar value. Specify **auto** for the Dashboard Scope to set the time span to the model simulation stop time.

### Y-Axis Limits

Vertical axis range.

### Settings

**Default:** -3 and 3

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Min** value must be less than the **Max** value.

### Legend

Position of the line legend.

### Settings

**Default:** Top

Top

Show the legend at the top of the plot.

Right

Show the legend at the right of the plot.

Hide

Do not show the legend.

### Scale axes limits at stop

Perform a fit-to-view on the data displayed in the scope when the simulation has stopped.

## Settings

**Default:** On

On

Perform a fit-to-view on the data displayed in the scope when the simulation has stopped.

Off

Do not perform a fit-to-view on the data displayed in the scope when the simulation has stopped.

## Show “Double-click to connect” message

Show instructional text if the block is not connected. You can clear the check box to hide the text when the block is not connected.

## Settings

**Default:** On

On

Show the instructional text if the block is not connected.

Off

Do not show the instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Data Store Memory

Define data store

### Library

Signal Routing

### Description

The Data Store Memory block defines and initializes a named shared data store, which is a memory region usable by Data Store Read and Data Store Write blocks that specify the same data store name.

The location of the Data Store Memory block that defines a data store determines which Data Store Read and Data Store Write blocks can access the data store:

- If the Data Store Memory block is in the *top-level system*, Data Store Read and Data Store Write blocks anywhere in the model can access the data store.
- If the Data Store Memory block is in a *subsystem*, Data Store Read and Data Store Write blocks in the same subsystem or in any subsystem below it in the model hierarchy can access the data store.

Data Store Read or Data Store Write blocks cannot access a Data Store Memory block that is either in a model that contains a Model block or in a referenced model.

Do not include a Data Store Memory block in a subsystem that a For Each Subsystem block represents.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see:

- “Order Data Store Access”

- “Data Store Diagnostics”
- “Log Data Stores”

You can use `Simulink.Signal` objects in addition to, or instead of, Data Store Memory blocks to define data stores. A data store defined in the *base* workspace with a signal object is a *global* data store. Global data stores are accessible to every model, including all referenced models. See “Data Stores” for more information.

## Data Type Support

The Data Store Memory block stores real or complex signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Bus

The block does not support variable-size signals.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

---

For more information, see “Data Types Supported by Simulink”.

You can use arrays of buses with a Data Store Memory block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Parameters

**Data store name**

Specify a name for the data store you are defining with this block. Data Store Read and Data Store Write blocks with the same name can read from, and write to, the data store initialized by this block. The name can represent a Data Store Memory block or a sign object defined to be a data store.

### Rename All

Rename the data store everywhere the Data Store Read and Data Store Write blocks use it in a model.

You cannot use **Rename All** to rename a data store if you:

- Use a `Simulink.Signal` object in a workspace to control the code generated for the data store
- Use a `Simulink.Signal` object instead of a Data Store Memory block to define the data store

You must instead rename the corresponding `Simulink.Signal` object from Model Explorer. For an example, see “Rename Data Store Defined by Signal Object”.

### Corresponding Data Store Read/Write blocks

List all the Data Store Read and Data Store Write blocks that have the same data store name as the current block, and that are in the current system or in any subsystem below it in the model hierarchy. Double-click a block in this list to highlight the block and bring it to the foreground.

### Initial value

Specify the initial value or values of the data store. The **Minimum** parameter specifies the minimum value for this parameter, and the **Maximum** parameter specifies the maximum value.

If you specify a nonscalar value and set **Dimensions** to -1 (the default), the data store has the same dimensions as the array. Data that you write to the data store (by using Data Store Write blocks) must have these dimensions.

If you set the **Dimensions** parameter to a value other than -1, the initial value dimensions must match the dimensions that you specify, unless the initial value is a scalar or a MATLAB structure. If you specify a scalar, each element of the data store uses the scalar as the initial value. Use this technique to apply the same initial value (the scalar that you specify) to each element without manually matching the dimensions of the initial value with the dimensions of the data store.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure and set the model configuration parameter “Underspecified initialization detection” to **Simplified**. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Signals”.

### Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the **Minimum** property of a bus element, see `Simulink.BusElement`.

---

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the **Maximum** property of a bus element, see `Simulink.BusElement`.

---

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Data type

Specify the output data type. You can set it to:

- A rule that inherits a data type (for example, `Inherit: auto`)
- The name of a built-in data type (for example, `single`)
- The name of a data type object (for example, a `Simulink.NumericType` object)
- An expression that evaluates to a data type (for example, `fixdt(1,16,0)`). Do not specify a bus object as the data type in an expression; use `Bus: <object name>` to specify a bus data type.
- `Bus: <object name>`; enter the name of a bus object that you want to use to define the structure of the bus. The bus must be a nonvirtual bus. If you need to create or change a bus object, click the **Show data type assistant** button and then click the **Edit** button to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter.

See “Control Signal Data Types”.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Signal type

Specify the numeric type, real or complex, of the values in the data store.

### Dimensions (-1 to infer from Initial value)

Dimensions of the data store. The default value, -1, enables you to set the dimensions of the data store by using the **Initial value** parameter. However, in this case, you cannot use scalar expansion with the initial value. You must specify the initial value by using an array that has the dimensions that you want.

If you use a value other than -1, specify the same dimensions as the dimensions of the **Initial value** parameter, unless you specify the initial value as a scalar (for scalar expansion) or a MATLAB structure. If the data store represents an array of buses, and if you use a MATLAB structure for the initial value, you can specify dimensions to initialize the array of buses with this structure.

### Interpret vector parameters as 1-D

Specify that the data store interpret vector initial values as one-dimensional.

By default, MATLAB represents vector data as matrices, which have two dimensions. For example, MATLAB represents the vector [1 2 3] as a 1-by-3 matrix.

When you select this parameter, the data store represents vector data by using only one dimension instead of two. For example, if you specify an initial value of [1 2 3], the data store stores a one-dimensional vector with three elements.

For more information, see “Determining the Output Dimensions of Source Blocks”.

### Data store must resolve to Simulink signal object

Specify that Simulink software, when compiling the model, searches the model and base workspace for a **Simulink.Signal** object having the same name, as described in “Symbol Resolution”. If Simulink does not find such an object, the compilation stops, with an error. Otherwise, Simulink compares the attributes of the signal object to the corresponding attributes of the Data Store Memory block. If the block and the object attributes are inconsistent, Simulink halts model compilation and displays an error.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package **mpt**, select **mpt.Signal**. Unless you use an ERT-based code generation target with Embedded Coder<sup>®</sup> software, custom storage classes do not affect the generated code.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage

classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### Storage class

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

---

**Note:** **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder software, custom storage classes and memory sections do not affect the generated code.

---

See “Discrete Block State Naming in Generated Code” (Simulink Coder) for more information.

### Detect read before write

Select the diagnostic action to take if the model attempts to read data from a data store to which it has not written data in this time step. See also the “Detect read before write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

**Default:** warning

none

Simulink software takes no action.

warning

Simulink software displays a warning and continues the simulation.

error

Simulink software terminates the simulation and displays an error.

### **Detect write after read**

Select the diagnostic action to take if the model attempts to write data to the data store after previously reading data from it in the current time step. See also the “Detect write after read” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

**Default:** warning

none

Simulink software takes no action.

warning

Simulink software displays a warning and continues the simulation.

error

Simulink software terminates the simulation and displays an error.

### **Detect write after write**

Select the diagnostic action to take if the model attempts to write data to the data store twice in succession in the current time step. See also the “Detect write after write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

**Default:** warning

none

Simulink software takes no action.

warning

Simulink software displays a warning and continues the simulation.

error

Simulink software terminates the simulation and displays an error.

### Log signal data

Select this option to save the values of this signal to the MATLAB workspace during simulation. See “Signal Logging” for details.

### Logging name

Use this pair of controls, consisting of a list box and an edit field, to specify the name associated with logged signal data.

Simulink uses the signal name as its logging name by default. To specify a custom logging name, select **Custom** from the list box and enter the custom name in the adjacent edit field.

### Data

Use this group of controls to limit the amount of data that Simulink logs for this signal.

- **Limit data points to last:** Discard all but the last N data points, where N is the number that you enter in the adjacent edit field.
- **Decimation:** Log every Nth data point, where N is the number that you enter in the adjacent edit field. For example, suppose that your model uses a fixed-step solver with a step size of 0.1 s. If you select this option and accept the default decimation value (2), Simulink records data points for this signal at times 0.0, 0.2, 0.4, and so on.

For more information, see “Log Data Stores”

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

## Data Store Read

Read data from data store

### Library

Signal Routing

### Description

The Data Store Read block copies data from the named data store to its output. More than one Data Store Read block can read from the same data store.

The data store from which the data is read is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. See “Order Data Store Access” and “Data Store Diagnostics” for details.

### Data Type Support

The Data Store Read block can output a real or complex signal of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

- Bus

The block does not support variable-size signals.

For more information, see “Data Types Supported by Simulink”.

You can use arrays of buses with a Data Store Read block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Parameters

### Data store name

Specifies the name of the data store from which this block reads data. The adjacent pull-down list lists the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Read block or at higher levels. The pulldown list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the pull-down list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink software searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink software does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. See “Symbol Resolution” for more information about the search path.

If Simulink software finds the signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value of 0. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error.

### Data store memory block

This field lists the Data Store Memory block that initialized the store from which this block reads.

### Data store write blocks

This parameter lists all the Data Store Write blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Double-click any entry on this list to highlight the block and bring it to the foreground.

### Sample time

The sample time, which controls when the block reads from the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Use the **Element Selection** pane to select a subset of the bus or matrix elements defined for the associated data store. The Data Store Read block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

### Elements in the array or Signals in the bus (Prompt is specific to the type of data.)

For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

For data stores with a bus data type, you can expand the tree to view the bus elements. For data stores with arrays, you can read the whole data store, or you can specify one or more elements of the whole data store.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the bus or matrix elements that you want to select for reading. Then click **Select>>**.

To refresh the display to reflect modifications to the bus or matrix used in the data store, click **Refresh**.

### Specify element(s) to select

Enter a MATLAB expression to define the specific element that you want to read. For example, for a data store named DSM that has maximum dimensions of [3, 5], you could enter expressions such as `DSM(2, 4)` or `DSM([1 3], 2)` in the edit box and then click **Select>>**.

To apply the element selection, click **OK**.

### Selected Element(s)

Displays the elements that you select. The Data Store Read block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

## Data Store Write

Write data to data store

### Library

Signal Routing

### Description

The Data Store Write block copies the value at its input to the named data store. Each write operation performed by a Data Store Write block writes over the data store, replacing the previous contents.

The data store to which this block writes is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and **Data Store Memory**. The size of the data store is set by the signal object or the Data Store Memory block that defines and initializes the data store. Each Data Store Write block that writes to that data store must write the same amount of data.

More than one Data Store Write block can write to the same data store. However, if two Data Store Write blocks attempt to write to the same data store during the same simulation step, results are unpredictable.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see “Order Data Store Access” and “Data Store Diagnostics”.

You can log the values of a local or global data store data variable for all the steps in a simulation. For details, see “Log Data Stores”.

## Data Type Support

The Data Store Write block accepts a real or complex signal of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Bus

The block does not support variable-size signals.

For more information, see “Data Types Supported by Simulink”.

You can use an array of buses with a Data Store Write block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Parameters

### Data store name

Specifies the name of the data store to which this block writes data. The adjacent pull-down list lists the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Write block or at higher levels. The pulldown list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the pull-down list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink software searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

If Simulink finds a signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial

value set to a matrix of zeros. The dimensions of that matrix are inherited from the **Dimensions** property of the signal object.

### Data store memory block

This field lists the Data Store Memory block that initialized the store to which this block writes.

### Data store read blocks

This parameter lists all the Data Store Read blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Double-click any entry on this list to highlight the block and bring it to the foreground.

### Sample time

Specify the sample time that controls when the block writes to the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Use the **Element Assignment** pane to assign a subset of the bus or matrix elements defined for writing to the associated data store. The Data Store Write block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

### Elements in the array or Signals in the bus (Prompt is specific to the type of data.)

For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

For data stores with a bus data type, you can expand the tree to view the bus elements. For data stores with arrays, you can write the whole data store, or you can assign one or more elements to the whole data store.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Assigned element(s)** list.
- Use the **Specify element(s) to assign** edit box to specify the bus or matrix elements that you want to select for reading. Then click **Select>>**.

To refresh the display to reflect modifications to the bus or matrix used in the data store, click **Refresh**.

### Specify element(s) to assign

Enter a MATLAB expression to define the specific element that you want to write. For example, for a data store named DSM that has maximum dimensions of [3, 5], you could enter expressions such as DSM(2, 4) or DSM([1 3], 2) in the edit box. Then click **Select>>**.

To apply the element selection, click **OK**.

### Assigned Element(s)

Displays the elements that you selected for assignment. The Data Store Write block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

## Data Type Conversion

Convert input signal to specified data type

### Library

Signal Attributes

### Description

The Data Type Conversion block converts an input signal of any Simulink data type to the data type that you specify.

The input can be any real- or complex-valued signal. If the input is real, the output is real. If the input is complex, the output is complex.

---

**Note** To control the output data type by specifying block parameters, or to inherit a data type from a downstream block, use the Data Type Conversion block. To inherit a data type from a different signal in the model, use the Data Type Conversion Inherited block.

---

### Convert Fixed-Point Signals

When you convert between fixed-point data types, the **Input and output to have equal** parameter controls block behavior. If neither input nor output use fixed-point scaling, because they are not of a fixed-point data type or have trivial fixed-point scaling, this parameter does not change the behavior of the block. For more information about fixed-point numbers, see “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).

To convert a signal from one data type to another by attempting to preserve the real-world value of the input signal, select **Real World Value (RWV)**, the default setting. The block accounts for the scaling of the input and output and, within the limits of the specified data types, attempts to generate an output of equal real-world value.

To change the real-world value of the input signal by performing a scaling reinterpretation of the stored integer value, select **Stored Integer (SI)**. Within the limits of the specified data types, the block attempts to preserve the stored integer value of the signal during conversion. A best practice is to specify input and output data types using the same word length and signedness so that the block changes only the scaling of the signal. Specifying a different signedness or word length for the input and output could produce unexpected results such as range loss or unexpected sign extensions. For an example, see “Reinterpret Signal Using a Fixed-Point Data Type” on page 1-272.

If you select **Stored Integer (SI)**, the block does not perform a lower-level bit reinterpretation of a floating-point input signal. For example, if the input is of the data type `single` and has value `5`, the bits that store the input in memory are given in hexadecimal by the following command.

```
num2hex(single(5))
40a00000
```

However, the Data Type Conversion block does not treat the stored integer value as `40a00000`, but instead as the real-world value, `5`. After conversion, the stored integer value of the output is `5`.

## Cast Enumerated Signals

Use a Data Type Conversion block to cast enumerated signals as follows:

- 1 To cast a signal of enumerated type to a signal of any numeric type.

The underlying integers of all enumerated values input to the Data Type Conversion block must be within the range of the numeric type. Otherwise, an error occurs during simulation.

- 2 To cast a signal of any integer type to a signal of enumerated type.

The value input to the Data Type Conversion block must match the underlying value of an enumerated value. Otherwise, an error occurs during simulation.

You can enable the block’s **Saturate on integer overflow** parameter so that Simulink uses the default value of the enumerated type when the value input to the block does not match the underlying value of an enumerated value. See “Type Casting for Enumerations” (Simulink Coder).

You cannot use a Data Type Conversion block in the following cases:

- To cast a non-integer numeric signal to an enumerated signal.
- To cast a complex signal to an enumerated signal, regardless of the data types of the complex signal's real and imaginary parts.

See “Simulink Enumerations” for information on working with enumerated types.

## Data Type Support

The Data Type Conversion block handles any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Input and output to have equal

Specify which type of input and output must be equal, in the context of fixed point data representation.

### Settings

**Default:** Real World Value (RWV)

Real World Value (RWV)

Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.

Stored Integer (SI)

Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

### Command-Line Information

For the command-line information, see “Block-Specific Parameters” on page 6-105.

Controlengineers.ir

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via back propagation

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**double**

Output data type is **double**.

**single**

Output data type is **single**.

**int8**

Output data type is **int8**.

**uint8**

Output data type is **uint8**.

**int16**

Output data type is **int16**.

**uint16**

Output data type is **uint16**.

**int32**

Output data type is **int32**.

**uint32**

Output data type is **uint32**.

**boolean**

Output data type is **boolean**. The Data Type Conversion block converts real, nonzero numeric values (including NaN and Inf) to **boolean true (1)**.

**fixdt(1,16,0)**

Output data type is fixed point **fixdt(1,16,0)**.

**fixdt(1,16,2^0,0)**

Output data type is fixed point **fixdt(1,16,2^0,0)**.

Enum: <class name>

Use an enumerated data type, for example, Enum: BasicColors.

<data type expression>

Use a data type object, for example, Simulink.NumericType.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables **Inherit** via back propagation.

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

ControlEngineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Examples

### Real-World Values and Stored Integers

The example model `ex_data_type_conversion_rwv_si` uses Data Type Conversion blocks to show the meaning of the real-world value and the stored integer of a signal. For basic information about fixed-point scaling, see “Scaling” (Fixed-Point Designer).

## Conversion Between Fixed-Point Data Types

The Fixed-Point Constant block represents the real-world value 15 by using a fixed-point data type with binary-point scaling  $2^{-5}$ . Due to the scaling, the output signal uses a stored integer value of 480.

The model uses Data Type Conversion blocks to convert the signal to a fixed-point data type with binary-point scaling  $2^{-2}$ .

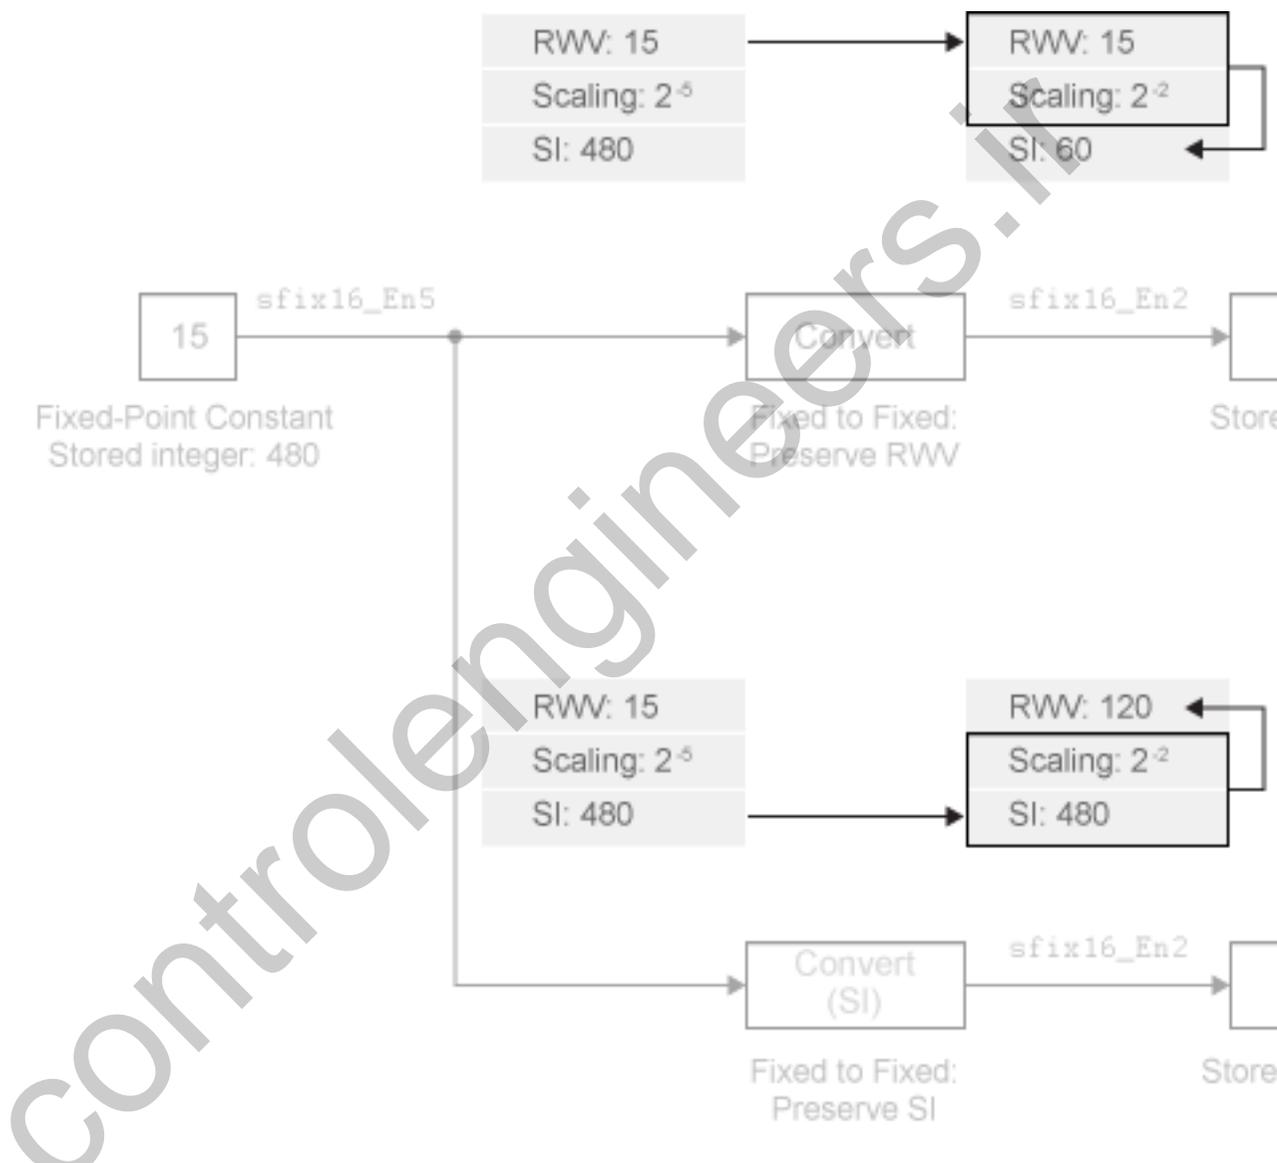

- The Fixed to Fixed: Preserve RWV block converts the input signal by preserving the real-world value, 15. The parameter **Input and output to have equal** is set to Real World Value (RWV).

The output signal has the same real-world value as the input, that is, 15. Due to the fixed-point scaling, the output uses a stored integer value of 60.

- The Fixed to Fixed: Preserve SI block converts the input signal by preserving the stored integer value, 480. The parameter **Input and output to have equal** is set to Stored Integer (SI).

The output signal uses the same stored integer value as the input, that is, 480. Due to the fixed-point scaling, the output has a real-world value of 120.

The figure shows the conversion mechanism for the two blocks.

**Conversion Between Floating-Point and Fixed-Point Data Type**

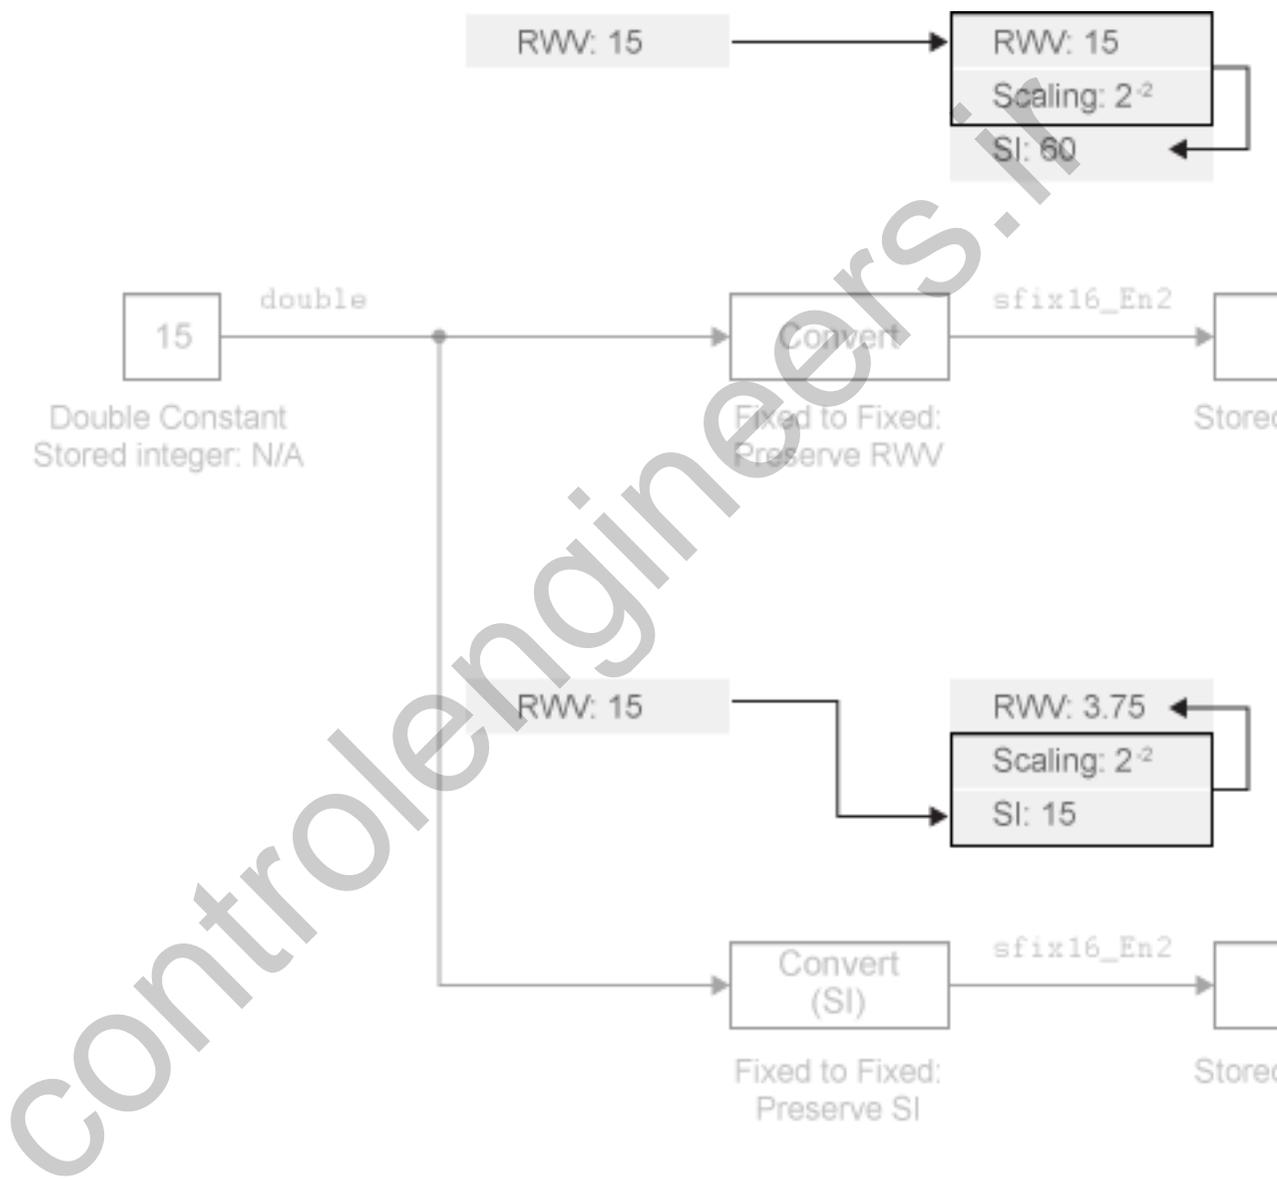

The Double Constant block represents the real-world value 15 by using the floating-point data type `double`. The output signal does not use fixed-point scaling.

The model uses Data Type Conversion blocks to convert the **double** signal to a fixed-point data type with binary-point scaling  $2^{-2}$ .

- The Float to Fixed: Preserve RWV block converts the input signal by preserving the real-world value, 15. The output signal has the same real-world value. Due to the fixed-point scaling, the output uses a stored integer value of 60.
- The Float to Fixed: Preserve SI block converts the input signal by attempting to preserve the stored integer value. However, the block does not use the underlying bits that store the floating-point signal in memory. Instead, the block uses the real-world value of the input, 15, as the stored integer of the output signal. Due to the fixed-point scaling, the real-world value of the output is 3.75.

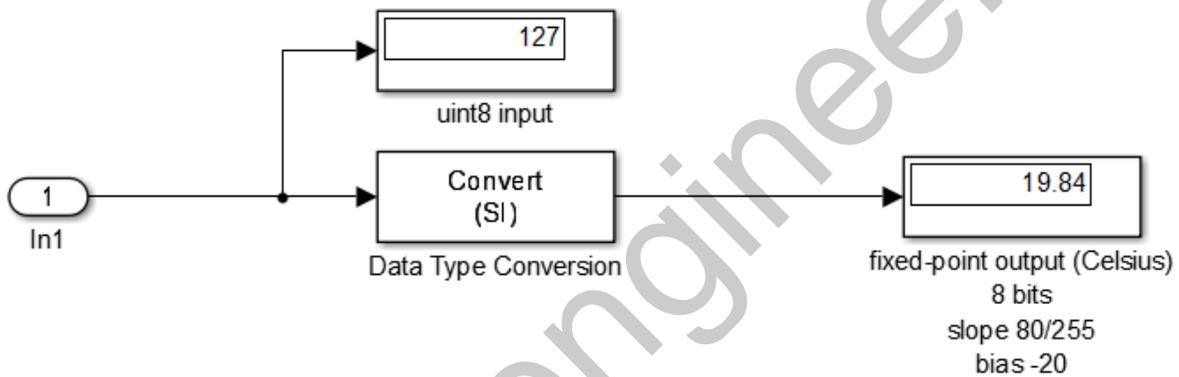

The figure shows the conversion mechanism for the two blocks. The blocks also use these mechanisms if the input uses the floating-point data type **single**.

Controlengineers.ir

## Reinterpret Signal Using a Fixed-Point Data Type

Suppose your hardware uses the data type `uint8` to store data from a temperature sensor. Also suppose that the minimum stored integer value 0 represents  $-20$  degrees Celsius while the maximum 255 represents 60 degrees. The following model uses a Data Type Conversion block to convert the stored integer value of the sensor data to degrees Celsius.

The Data Type Conversion block parameter **Input and output to have equal** is set to **Stored Integer (SI)**. The block output signal is of a fixed-point data type with word length 8, slope 80/255, and bias -20.

The Data Type Conversion block reinterprets the integer input, 127, as a Celsius output, 19.84 degrees. The block output uses the specified slope and bias to scale the stored integer of the input.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes

Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Controlengineers.ir

## Data Type Conversion Inherited

Convert from one data type to another using inherited data type and scaling

### Library

Signal Attributes

### Description

The Data Type Conversion Inherited block forces dissimilar data types to be the same. The first input is used as the reference signal and the second input is converted to the reference type by inheriting the data type and scaling information. (See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.) Either input undergoes scalar expansion such that the output has the same width as the widest input.

Inheriting the data type and scaling provides these advantages:

- It makes reusing existing models easier.
- It allows you to create new fixed-point models with less effort since you can avoid the detail of specifying the associated parameters.

### Data Type Support

The Data Type Conversion Inherited block accepts signals of the following data types:

- Floating point
- Built-in integer

- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Input and Output to have equal

Specify whether the Real World Value (RWV) or the Stored Integer (SI) of the input and output should be the same. Refer to Description in the Data Type Conversion block reference page for more information about these choices.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes

## Data Type Duplicate

Force all inputs to same data type

## Library

Signal Attributes

## Description

The Data Type Duplicate block forces all inputs to have exactly the same data type. Other attributes of input signals, such as dimension, complexity, and sample time, are completely independent.

You can use the Data Type Duplicate block to check for consistency of data types among blocks. If all signals do not have the same data type, the block returns an error message.

The Data Type Duplicate block is typically used such that one signal to the block controls the data type for all other blocks. The other blocks are set to inherit their data types via back propagation.

The block is also used in a user created library. These library blocks can be placed in any model, and the data type for all library blocks are configured according to the usage in the model. To create a library block with more complex data type rules than duplication, use the Data Type Propagation block.

## Data Type Support

The Data Type Duplicate block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Number of input ports

Specify the number of inputs to this block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# Data Type Propagation

Set data type and scaling of propagated signal based on information from reference signals

## Library

Signal Attributes

## Description

The Data Type Propagation block allows you to control the data type and scaling of signals in your model. You can use this block in conjunction with fixed-point blocks that have their **Output data type** parameter configured to **Inherit: Inherit via back propagation**.

The block has three inputs: Ref1 and Ref2 are the reference inputs, while the Prop input back propagates the data type and scaling information gathered from the reference inputs. This information is then passed on to other fixed-point blocks.

The block provides you with many choices for propagating data type and scaling information. For example, you can:

- Use the number of bits from the Ref1 reference signal, or use the number of bits from widest reference signal.
- Use the range from the Ref2 reference signal, or use the range of the reference signal with the greatest range.
- Use a bias of zero, regardless of the biases used by the reference signals.
- Use the precision of the reference signal with the least precision.

You specify how data type information is propagated with the **Propagated data type** parameter list. If the parameter list is configured as **Specify via dialog**, then you manually specify the data type via the **Propagated data type** edit field. If the parameter list is configured as **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-281.

You specify how scaling information is propagated with the **Propagated scaling** parameter list. If the parameter list is configured as **Specify via dialog**, then you manually specify the scaling via the **Propagated scaling** edit field. If the parameter list is configured as **Inherit via propagation rule**, then you must use the parameters described in “Parameters” on page 1-281.

After you use the information from the reference signals, you can apply a second level of adjustments to the data type and scaling by using individual multiplicative and additive adjustments. This flexibility has a variety of uses. For example, if you are targeting a DSP, then you can configure the block so that the number of bits associated with a MAC (multiply and accumulate) operation is twice as wide as the input signal, and has a certain number of guard bits added to it.

The Data Type Propagation block also provides a mechanism to force the computed number of bits to a useful value. For example, if you are targeting a 16-bit micro, then the target C compiler is likely to support sizes of only 8 bits, 16 bits, and 32 bits. The block will force these three choices to be used. For example, suppose the block computes a data type size of 24 bits. Since 24 bits is not directly usable by the target chip, the signal is forced up to 32 bits, which is natively supported.

There is also a method for dealing with floating-point reference signals. This makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or vice versa.

The Data Type Propagation block allows you to set up libraries of useful subsystems that will be properly configured based on the connected signals. Without this data type propagation process, a subsystem that you use from a library will almost certainly not work as desired with most integer or fixed-point signals, and manual intervention to configure the data type and scaling would be required. This block can eliminate the manual intervention in many situations.

## Precedence Rules

The precedence of the dialog box parameters decreases from top to bottom. Additionally:

- Double-precision reference inputs have precedence over all other data types.
- Single-precision reference inputs have precedence over integer and fixed-point data types.
- Multiplicative adjustments are carried out before additive adjustments.
- The number of bits is determined before the precision or positive range is inherited from the reference inputs.

## Data Type Support

The Data Type Propagation block accepts signals of the following data types:

- Floating-point
- Built-in integer
- Fixed-point
- Boolean

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Propagated data type

Use the parameter list to propagate the data type via the dialog box, or inherit the data type from the reference signals. Use the edit field to specify the data type via the dialog box.

### If any reference input is double, output is

Specify **single** or **double**. This parameter makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or vice versa.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

### If any reference input is single, output is

Specify **single** or **double**. This parameter makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or visa versa.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

### Is-Signed

Specify the sign of Prop as one of the following values:

Parameter Value	Description
IsSigned1	Prop is a signed data type if Ref1 is a signed data type.
IsSigned2	Prop is a signed data type if Ref2 is a signed data type.
IsSigned1 or IsSigned2	Prop is a signed data type if either Ref1 or Ref2 are signed data types.
TRUE	Ref1 and Ref2 are ignored, and Prop is always a signed data type.
FALSE	Ref1 and Ref2 are ignored, and Prop is always an unsigned data type.

For example, if the Ref1 signal is `ufix(16)`, the Ref2 signal is `sfix(16)`, and the **Is-Signed** parameter is **IsSigned1 or IsSigned2**, then Prop is forced to be a signed data type.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

### Number-of-bits: Base

Specify the number of bits used by Prop for the base data type as one of the following values:

Parameter Value	Description
NumBits1	The number of bits for Prop is given by the number of bits for Ref1.
NumBits2	The number of bits for Prop is given by the number of bits for Ref2.
<code>max([NumBits1 NumBits2])</code>	The number of bits for Prop is given by the reference signal with largest number of bits.
<code>min([NumBits1 NumBits2])</code>	The number of bits for Prop is given by the reference signal with smallest number of bits.

Parameter Value	Description
NumBits1+NumBits2	The number of bits for Prop is given by the sum of the reference signal bits.

For more information about the base data type, refer to Targeting an Embedded Processor (Fixed-Point Designer).

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

#### Number-of-bits: Multiplicative adjustment

Specify the number of bits used by Prop by including a multiplicative adjustment that uses a data type of **double**. For example, suppose you want to guarantee that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal. To do this, you configure this parameter to the value 2.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

#### Number-of-bits: Additive adjustment

Specify the number of bits used by Prop by including an additive adjustment that uses a data type of **double**. For example, if you are performing multiple additions during a MAC operation, the result might overflow. To prevent overflow, you can associate guard bits with the propagated data type. To associate four guard bits, you specify the value 4.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

#### Number-of-bits: Allowable final values

Force the computed number of bits used by Prop to a useful value. For example, if you are targeting a processor that supports only 8, 16, and 32 bits, then you configure this parameter to [8, 16, 32]. The block always propagates the smallest specified value that fits. If you want to allow all fixed-point data types, you would specify the value 1:128.

This parameter is visible only when you set **Propagated data type** to **Inherit** via propagation rule.

#### Propagated scaling

Use the parameter list to propagate the scaling via the dialog box, inherit the scaling from the reference signals, or calculate the scaling to obtain best precision.

**Propagated scaling (Slope or [Slope Bias])**

Specify the scaling as either a slope or a slope and bias.

This parameter is visible only when you set **Propagated scaling** to **Specify** via dialog.

**Values used to determine best precision scaling**

Specify any values to be used to constrain the precision, such as the upper and lower limits on the propagated input. Based on the data type, the scaling will automatically be selected such that these values can be represented with no overflow error and minimum quantization error.

This parameter is visible only when you set **Propagated scaling** to **Obtain** via best precision.

**Slope: Base**

Specify the slope used by Prop for the base data type as one of the following values:

Parameter Value	Description
Slope1	The slope of Prop is given by the slope of Ref1.
Slope2	The slope of Prop is given by the slope of Ref2.
max([Slope1 Slope2])	The slope of Prop is given by the maximum slope of the reference signals.
min([Slope1 Slope2])	The slope of Prop is given by the minimum slope of the reference signals.
Slope1*Slope2	The slope of Prop is given by the product of the reference signal slopes.
Slope1/Slope2	The slope of Prop is given by the ratio of the Ref1 slope to the Ref2 slope.
PosRange1	The range of Prop is given by the range of Ref1.
PosRange2	The range of Prop is given by the range of Ref2.
max([PosRange1 PosRange2])	The range of Prop is given by the maximum range of the reference signals.
min([PosRange1 PosRange2])	The range of Prop is given by the minimum range of the reference signals.

Parameter Value	Description
PosRange1*PosRange2	The range of Prop is given by the product of the reference signal ranges.
PosRange1 / PosRange2	The range of Prop is given by the ratio of the Ref1 range to the Ref2 range.

You control the precision of Prop with **Slope1** and **Slope2**, and you control the range of Prop with **PosRange1** and **PosRange2**. Additionally, **PosRange1** and **PosRange2** are one bit higher than the maximum positive range of the associated reference signal.

This parameter is visible only when you set **Propagated scaling** to **Inherit** via propagation rule.

#### **Slope: Multiplicative adjustment**

Specify the slope used by Prop by including a multiplicative adjustment that uses a data type of **double**. For example, if you want 3 bits of additional precision (with a corresponding decrease in range), the multiplicative adjustment is  $2^{-3}$ .

This parameter is visible only when you set **Propagated scaling** to **Inherit** via propagation rule.

#### **Slope: Additive adjustment**

Specify the slope used by Prop by including an additive adjustment that uses a data type of **double**. An additive slope adjustment is often not needed. The most likely use is to set the multiplicative adjustment to 0, and set the additive adjustment to force the final slope to a specified value.

This parameter is visible only when you set **Propagated scaling** to **Inherit** via propagation rule.

#### **Bias: Base**

Specify the bias used by Prop for the base data type. The parameter values are described as follows:

Parameter Value	Description
Bias1	The bias of Prop is given by the bias of Ref1.
Bias2	The bias of Prop is given by the bias of Ref2.
max([Bias1 Bias2])	The bias of Prop is given by the maximum bias of the reference signals.

Parameter Value	Description
<code>min([Bias1 Bias2])</code>	The bias of Prop is given by the minimum bias of the reference signals.
<code>Bias1*Bias2</code>	The bias of Prop is given by the product of the reference signal biases.
<code>Bias1/Bias2</code>	The bias of Prop is given by the ratio of the Ref1 bias to the Ref2 bias.
<code>Bias1+Bias2</code>	The bias of Prop is given by the sum of the reference biases.
<code>Bias1-Bias2</code>	The bias of Prop is given by the difference of the reference biases.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

#### **Bias: Multiplicative adjustment**

Specify the bias used by Prop by including a multiplicative adjustment that uses a data type of `double`.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

#### **Bias: Additive adjustment**

Specify the bias used by Prop by including an additive adjustment that uses a data type of `double`.

If you want to guarantee that the bias associated with Prop is zero, you should configure both the multiplicative adjustment and the additive adjustment to `0`.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

## Data Type Scaling Strip

Remove scaling and map to built in integer

### Library

Signal Attributes

### Description

The Scaling Strip block strips the scaling off a fixed point signal. It maps the input data type to the smallest built in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output. The output always has nominal scaling (slope = 1.0 and bias = 0.0), so the output does not make a distinction between real world value and stored integer value.

### Data Type Support

The Data Type Scaling Strip block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

### Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes

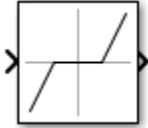

Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

## Dead Zone

Provide region of zero output

## Library

Discontinuities

## Description

The Dead Zone block generates zero output within a specified region, called its dead zone. You specify the lower limit (LL) and upper limit (UL) of the dead zone as the **Start of dead zone** and **End of dead zone** parameters, respectively. The block output depends on the input (U) and the values for the lower and upper limits:

Input	Output
$U \geq LL$ and $U \leq UL$	Zero
$U > UL$	$U - UL$
$U < LL$	$U - LL$

## Data Type Support

The Dead Zone block accepts and outputs real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Start of dead zone

Specify the lower limit of the dead zone. The default is -0.5.

### End of dead zone

Specify the upper limit of the dead zone. The default is 0.5.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For

Action	Reasons for Taking This Action	What Happens for Overflows	Example
			example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Treat as gain when linearizing

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1; otherwise, the commands treat the gain as 0.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

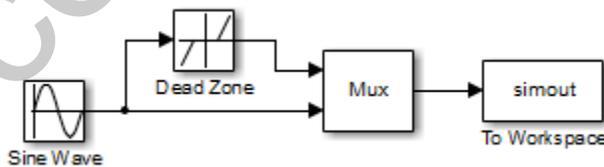

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

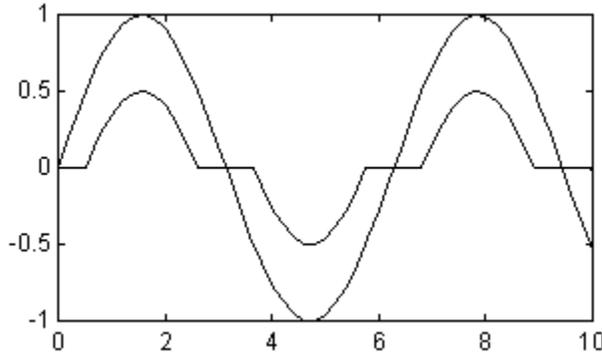

---

## Examples

The following model uses lower and upper limits of -0.5 and 0.5, with a sine wave as input.

This plot shows the effect of the Dead Zone block on the sine wave. When the input sine wave is between  $-0.5$  and  $0.5$ , the output is zero.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

Dead Zone Dynamic

Introduced before R2006a

## Dead Zone Dynamic

Set inputs within bounds to zero

### Library

Discontinuities

### Description

The Dead Zone Dynamic block dynamically bounds the range of the input signal, providing a region of zero output. The bounds change according to the upper and lower limit input signals where

- The input within the bounds is set to zero.
- The input below the lower limit is shifted down by the lower limit.
- The input above the upper limit is shifted down by the upper limit.

The input for the upper limit is the **up** port, and the input for the lower limit is the **lo** port.

### Data Type Support

The Dead Zone Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point

## Decrement Real World

Decrease real world value of signal by one

### Library

Additional Math & Discrete / Additional Math: Increment - Decrement

### Description

The Decrement Real World block decreases the real world value of the signal by one. Overflows always wrap.

### Data Type Support

The Decrement Real World block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Direct Feedthrough	Yes

Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## Decrement Stored Integer

Decrease stored integer value of signal by one

### Library

Additional Math & Discrete / Additional Math: Increment - Decrement

### Description

The Decrement Stored Integer block decreases the stored integer value of a signal by one.

Floating-point signals also decrease by one, and overflows always wrap.

### Data Type Support

The Decrement Stored Integer block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
------------	--

Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes

## Decrement Time To Zero

Decrease real-world value of signal by sample time, but only to zero

### Library

Additional Math & Discrete / Additional Math: Increment - Decrement

### Description

The Decrement Time To Zero block decreases the real-world value of the signal by the sample time,  $T_s$ . The output never goes below zero. This block works only with fixed sample rates and does not work inside a triggered subsystem.

### Data Type Support

The Decrement Time To Zero block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
------------	--

Direct Feedthrough	Yes

## Delay

Delay input signal by fixed or variable sample periods

## Library

Discrete

## Description

The Delay block outputs the input of the block after a delay. The block determines the delay time based on the value of the **Delay length** parameter. The block supports:

- Variable delay length
- Specification of the initial condition from an input port
- State storage
- Using a circular buffer instead of an array buffer for state storage
- Resetting the state to the initial condition with an external reset signal
- Controlling execution of the block at every time step with an external enable signal

The initial block output depends on a number of factors such as the **Initial condition** parameter and the simulation start time. For more information, see “Initial Block Output” on page 1-304. The **External reset** parameter determines if the block output resets to the initial condition on triggering. The **Show enable port** parameter determines if the block execution is controlled in every time step by an external enable signal.

## Initial Block Output

The output of the Delay block in the first few time steps of the simulation depends on the block sample time, the delay length, and the simulation start time. The block supports

specifying or inheriting discrete sample times to determine the time interval between samples. For more information, see “Specify Sample Time”.

Suppose that the block inherits a discrete sample time as  $[T_{sampling}, T_{offset}]$ , where  $T_{sampling}$  is the sampling period and  $T_{offset}$  is the initial time offset.  $n$  is the value of the block’s **Delay length** parameter and  $T_{start}$  is the simulation start time for the model.

The table shows the Delay block output for the first few time steps.

Simulation Time Range	Block Output
$(T_{start})$ to $(T_{start} + T_{offset})$	Zero
$(T_{start} + T_{offset})$ to $(T_{start} + T_{offset} + n * T_{sampling})$	Initial condition parameter
After $(T_{start} + T_{offset} + n * T_{sampling})$	Input signal

## Data Type Support

The block’s parameters have these dimensional requirements:

- **Delay length** and **External reset** must be scalar.
- **Initial condition** can be scalar or nonscalar.
- For frame-based processing, signal dimensions of the data input port  $u$  cannot be larger than two.

The block supports input signals with these data types.

Input Signal	Supported Data Types
Data input port $u$	<ul style="list-style-type: none"> <li>• Floating point</li> <li>• Built-in integer</li> <li>• Fixed point</li> <li>• Boolean</li> <li>• Enumerated</li> </ul>
Delay length $d$	<ul style="list-style-type: none"> <li>• Floating point</li> </ul>

Input Signal	Supported Data Types
	<ul style="list-style-type: none"> <li>• Fixed-point integer</li> <li>• Built-in integer</li> </ul>
Enable port 	<ul style="list-style-type: none"> <li>• Floating point</li> <li>• Built-in integer</li> <li>• Fixed point Integer (only <code>ufix1</code>)</li> <li>• Boolean</li> </ul>
External reset port 	<ul style="list-style-type: none"> <li>• Floating point</li> <li>• Built-in integer</li> <li>• Fixed point Integer (only <code>ufix1</code>)</li> <li>• Boolean</li> </ul>
Initial condition <code>x0</code>	<ul style="list-style-type: none"> <li>• Floating point</li> <li>• Built-in integer</li> <li>• Fixed point</li> <li>• Boolean</li> <li>• Enumerated</li> </ul>

When `u` is Boolean, `x0` must be Boolean. When `u` uses an enumerated type, `x0` must use the same enumerated type. Otherwise, `x0` can use a floating-point, built-in integer, or fixed-point data type that fits in the data type of `u`. For example, when `u` uses `int32`, `x0` can use `int8` but not `double`.

The data type of the output signal is the same as the input signal `u`.

For more information, see “Data Types Supported by Simulink”.

## Variable-Size Support

The Delay block provides the following support for variable-size signals:

- The data input port `u` accepts variable-size signals. The other input ports do not accept variable-size signals.
- The output port has the same signal dimensions as the data input port `u` for variable-size inputs.

The rules that apply to variable-size signals depend on the input processing mode of the Delay block.

Input Processing Mode	Rules for Variable-Size Signal Support
Elements as channels (sample based)	<ul style="list-style-type: none"> <li>The signal dimensions change only during state reset when the block is enabled.</li> <li>The initial condition must be scalar.</li> </ul>
Columns as channels (frame based)	<ul style="list-style-type: none"> <li>No support</li> </ul>
Inherited (where input is a sample-based signal)	<ul style="list-style-type: none"> <li>The signal dimensions change only during state reset when the block is enabled.</li> <li>The initial condition must be scalar.</li> </ul>
Inherited (where input is a frame-based signal)	<ul style="list-style-type: none"> <li>The channel size changes only during state reset when the block is enabled.</li> <li>The initial condition must be scalar.</li> <li>The frame size must be constant.</li> </ul>

## Bus Support

The Delay block provides the following support for bus signals:

- The data input port  $u$  accepts virtual and nonvirtual bus signals. The other input ports do not accept bus signals.
- The output port has the same bus type as the data input port  $u$  for bus inputs.
- Buses work with:
  - Sample-based and frame-based processing
  - Fixed and variable delay length
  - Array and circular buffers

To use a bus signal as the input to a Delay block, you should specify the initial condition on the dialog box. In other words, the initial condition cannot come from the input port  $x0$ . Support for virtual and nonvirtual buses depends on the initial condition that you specify and whether the **State name** parameter is empty or not.

Initial Condition	State Name	
	Empty	Not Empty
Zero	Virtual and nonvirtual bus support	Nonvirtual bus support only
Nonzero scalar	Virtual and nonvirtual bus support	No bus support
Nonscalar	No bus support	No bus support
Structure	Virtual and nonvirtual bus support	Nonvirtual bus support only
Partial structure	Virtual and nonvirtual bus support	Nonvirtual bus support only

## Parameters

### Delay length

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to **Dialog**, enter the delay length in the edit field under **Value**.
- If you set **Source** to **Input port**, verify that an upstream signal supplies a delay length for the **d** input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A non-integer value from an input port (variable delay) truncates it to the integer.

This parameter is not tunable for simulation or code generation.

### Initial condition

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to **Dialog**, enter the initial condition in the edit field under **Value**.

- If you set **Source** to **Input port**, verify that an upstream signal supplies an initial condition for the x0 input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal **u** using a round-to-nearest operation and saturation.

---

**Note:** When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is **Input port**, the block ignores the initial value of the signal object.

---

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

---

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

---

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input **u**. All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Use circular buffer for state

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed:

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

### Prevent direct feedthrough

Select to increase the delay length from zero to the lower limit for the **Input processing** mode:

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port,  $u$ , to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port,  $x0$ , to the output port.

This check box is available when you set **Delay length: Source** to Input port.

## Remove delay length check in generated code

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

This check box is available when you set **Delay length: Source** to **Input port**.

## Diagnostic for delay length

Specify whether to produce a warning or error when the input  $d$  is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- **None** — Simulink software takes no action.
- **Warning** — Simulink software displays a warning and continues the simulation.
- **Error** — Simulink software terminates the simulation and displays an error.

This parameter is available when you set **Delay length: Source** to **Input port**.

## Show enable port

Select to show an enable port for this block. This port can control execution of the block. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

## External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> <li>• when the reset signal is nonzero at the current time step</li> <li>• when the reset signal value changes from nonzero at the previous time step to zero at the current time step</li> </ul>
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type **single**, **double**, **boolean**, or **integer**. Fixed point data types, except for **ufix1**, are not supported.

#### Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. This block supports discrete sample time, but not continuous sample time.

#### State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than **None**.

Selecting this check box disables **Code generation storage class**.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Code generation storage class

Select state storage class for code generation.

**Default:** Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

*StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

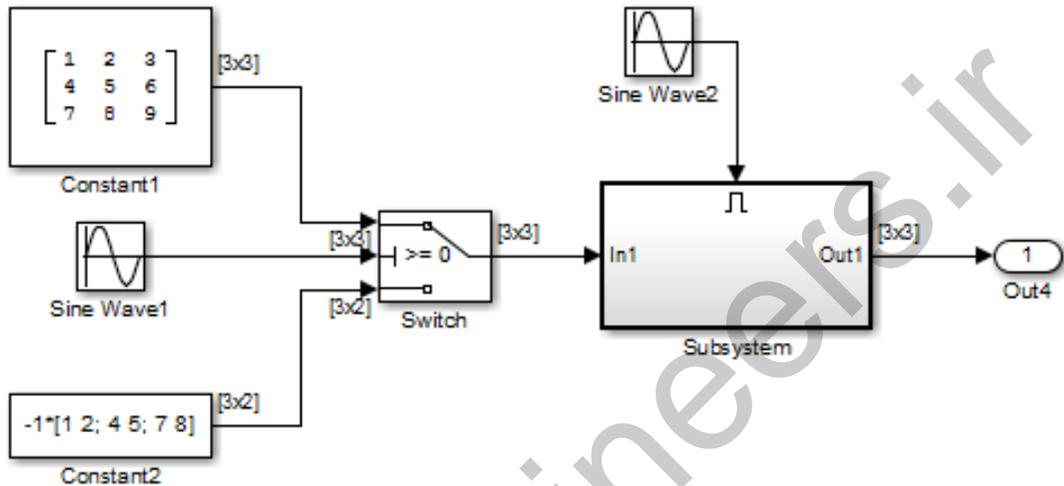

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

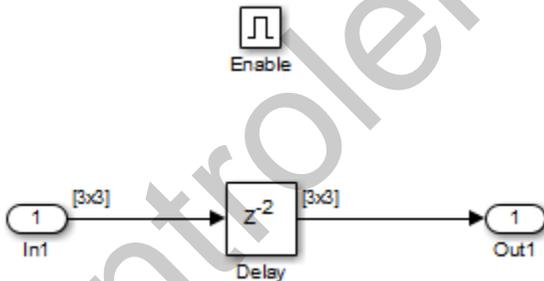

## Examples

### Variable-Size Signals for Sample-Based Processing

This model shows how the Delay block supports variable-size signals for sample-based processing.

The Switch block controls whether the input signal to the enabled subsystem is a 3-by-3 or 3-by-2 matrix. The Delay block appears inside the enabled subsystem.

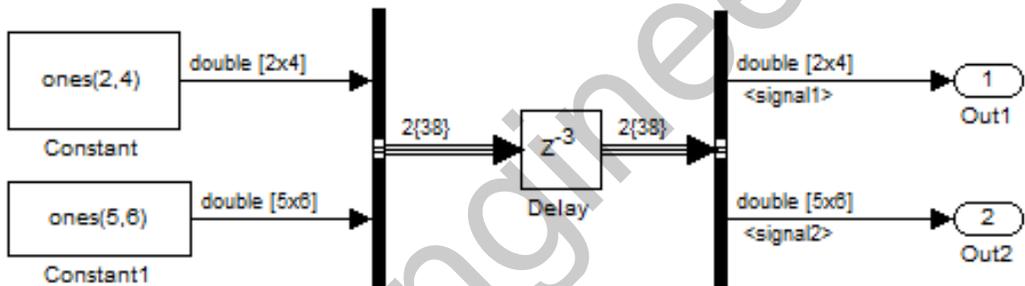

The model follows the rules for variable-size signals when the Delay block uses sample-based processing.

Rule	How the Model Follows the Rule
The signal dimensions change only during state reset when the block is enabled.	The Enable block sets <b>Propagate sizes of variable-size signals</b> to Only when enabling.

Rule	How the Model Follows the Rule
The initial condition must be scalar.	The Delay block sets <b>Initial condition</b> to 0.0, a scalar value.

## Bus Signals for Frame-Based Processing

This model shows how the Delay block supports bus signals for frame-based processing.

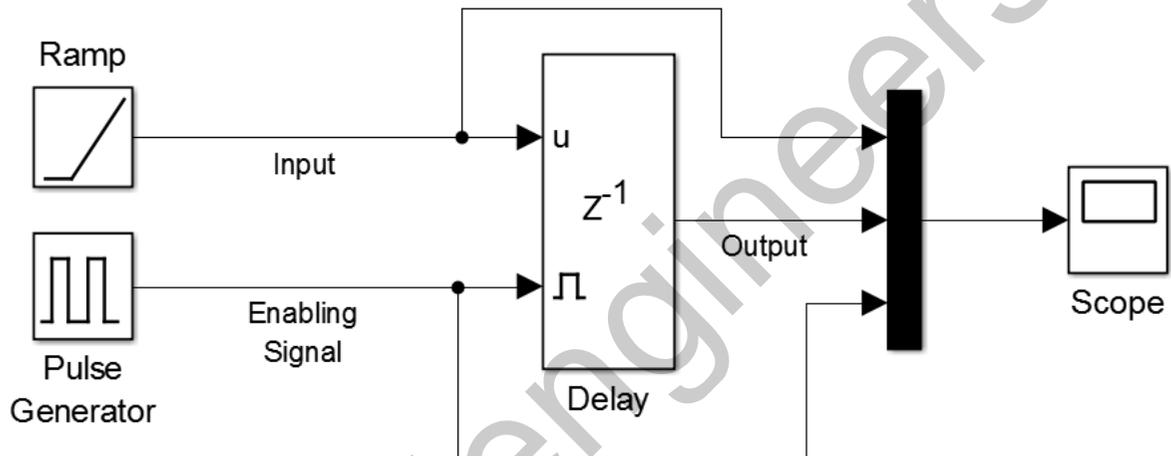

Each Constant block supplies an input signal to the Bus Creator block, which outputs a two-dimensional bus signal. After the Delay block delays the bus signal by three sample periods, the Bus Selector block separates the bus back into the two original signals.

The model follows the rules for bus signals when the Delay block uses frame-based processing.

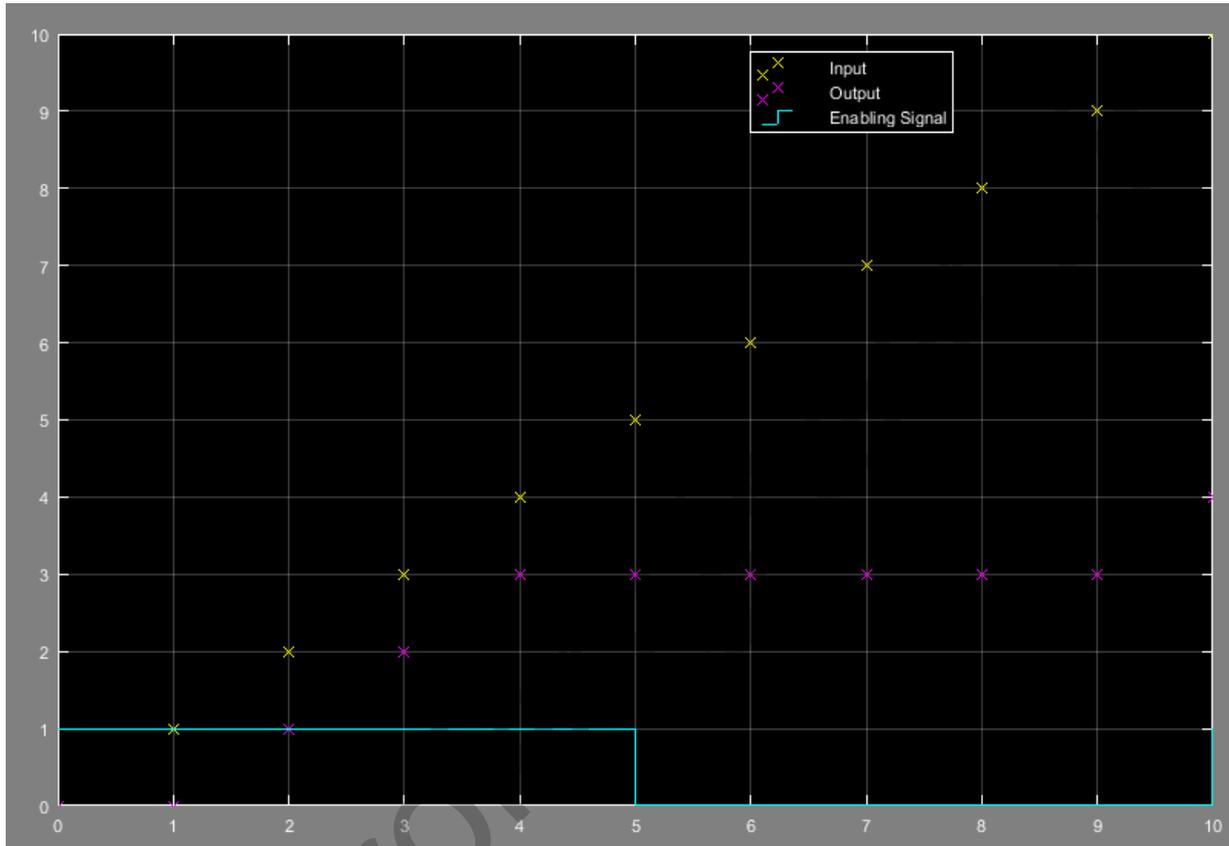

Rule	How the Model Follows the Rule
For the initial condition, set the value on the dialog box.	The Delay block sets <b>Initial condition</b> to 0, a scalar value.
For frame-based processing, signal dimensions of the data input port $u$ cannot be larger than two. (This rule applies to all inputs for the port $u$ , not just bus signals.)	The bus input to the Delay block has two dimensions.

## Enable or Disable Execution of the Delay Block

This example shows how you can enable or disable the execution of the Delay block using the enable port of the block. Consider this model. A ramp input signal feeds into a Delay block whose execution is controlled by an enabling signal. A Pulse Generator block generates this enabling signal.

The Scope block displays the output of the Delay block along with the enabling signal and the ramp input. Simulating the model and viewing the scope output shows the following graph.

The magenta marks show that the Delay block outputs the input signal delayed by one time step only while the enabling signal is 1. At  $t=5$  sec, the enabling signal becomes 0 and the Delay block does not execute. Hence, the output is held constant until the next time the enabling signal becomes 1.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter

Direct Feedthrough	Yes, when you clear <b>Prevent direct feedthrough</b>
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## Demux

Extract and output elements of vector signal

### Library

Signal Routing

### Description

The Demux block extracts the components of an input signal and outputs the components as separate signals. The output signals are ordered from top to bottom output port. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations. To avoid adding clutter to a model, Simulink hides the name of a Demux block when you copy it from the Simulink library to a model. See “Mux Signals” for information about creating and decomposing vectors.

The **Number of outputs** parameter allows you to specify the number and, optionally, the dimensionality of each output port. If you do not specify the dimensionality of the outputs, the block determines the dimensionality of the outputs for you.

---

**Tip:** If you specify a scalar for the **Number of outputs** parameter and all of the output ports are connected, as you draw a new signal line close to output side of a Demux block, Simulink adds a port and updates the **Number of outputs** parameter.

---

### Specify the Number of Outputs

The **Number of outputs** parameter value can be a scalar specifying the number of outputs or a vector whose elements specify the widths of the block output ports. The

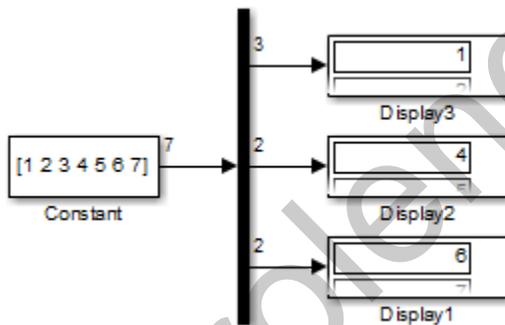

block determines the size of its outputs from the size of the input signal and the value of the **Number of outputs** parameter.

The following table summarizes how the block determines the outputs for an input vector of width  $n$ .

Parameter Value	Block outputs...	Comments
$p = n$	$p$ scalar signals	For example, if the input is a three-element vector and you specify three outputs, the block outputs three scalar signals.
$p > n$	Error	
$p < n$ $n \bmod p = 0$	$p$ vector signals each having $n/p$ elements	If the input is a six-element vector and you specify three outputs, the block outputs three two-element vectors.
$p < n$ $n \bmod p = m$	$m$ vector signals each having $(n/p)+1$ elements and $p-m$ signals having $n/p$ elements	If the input is a five-element vector and you specify three outputs, the block outputs two two-element vector signals and one scalar signal.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1+p_2+\dots+p_m=n$ $p_i > 0$	$m$ vector signals having widths $p_1, p_2, \dots, p_m$	If the input is a five-element vector and you specify $[3, 2]$ as the output, the block outputs three of the input elements on one port and the other two elements on the other port.
An array that has one or more of $m$ elements with a value of $-1$ , which specifies that Simulink infers the size for the element.  For example, suppose that you have a four-element array with a total width of 14 and you specify the parameter to be $[p_1 \ p_2 \ -1 \ p_4]$ .	$m$ vector signals	If $p_i$ is greater than zero, the corresponding output has width $p_i$ . If $p_i$ is $-1$ , the width of the corresponding output is computed dynamically.

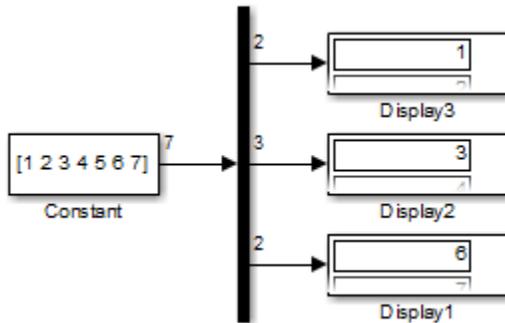

Parameter Value	Block outputs...	Comments
The value for the third element (the -1 element) is $14 - (p_1 + p_2 + p_4)$		
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1 + p_2 + \dots + p_m \neq n$ $p_i = > 0$	Error	

You can specify the number of outputs as fewer than the number of input elements, in which case the block distributes the elements as evenly as possible over the outputs. For example:

You can use  $-1$  in a vector expression to indicate that the block dynamically sizes the corresponding port. For example, the expression  $[-1, 3 -1]$  causes the block to output three signals where the second signal always has three elements. The sizes of the first and third signals depend on the size of the input signal.

If a vector expression comprises positive values and  $-1$  values, the block assigns as many elements as needed to the ports with positive values. The block distributes the remaining elements as evenly as possible over the ports with  $-1$  values. For example, suppose that the block input is seven elements wide and you specify the output as  $[-1, 3 -1]$ . In this case, the block outputs two elements on the first port, three elements on the second, and two elements on the third.

## Data Type Support

The Demux block accepts and outputs complex or real signals of any nonbus data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of outputs

Specify the number or number and dimensions of outputs. For details, see “Specify the Number of Outputs” on page 1-320.

### Settings

#### Default: 2

Specify a scalar for the number of outputs or a vector whose elements specify the widths of the block output ports.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

**See Also**

## Derivative

Output time derivative of input

## Library

Continuous

## Description

The Derivative block approximates the derivative of the input signal  $u$  with respect to the simulation time  $t$ . You obtain the approximation of

$$\frac{du}{dt},$$

by computing a numerical difference  $\Delta u/\Delta t$ , where  $\Delta u$  is the change in input value and  $\Delta t$  is the change in time since the previous simulation (major) time step.

This block accepts one input and generates one output. The initial output for the block is zero.

The precise relationship between the input and output of this block is:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}},$$

where  $t$  is the current simulation time and  $T_{previous}$  is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

The Derivative block output might be very sensitive to the dynamics of the entire model. The accuracy of the output signal depends on the size of the time steps taken in the simulation. Smaller steps allow a smoother and more accurate output curve from this

block. However, unlike with blocks that have continuous states, the solver does not take smaller steps when the input to this block changes rapidly. Depending on the dynamics of the driving signal and model, the output signal of this block might contain unexpected fluctuations. These fluctuations are primarily due to the driving signal output and solver step size.

Because of these sensitivities, structure your models to use integrators (such as **Integrator** blocks) instead of Derivative blocks. Integrator blocks have states that allow solvers to adjust step size and improve accuracy of the simulation. See “Circuit Model” for an example of choosing the best-form mathematical model to avoid using Derivative blocks in your models,

If you must use the Derivative block with a variable step solver, set the solver maximum step size settings to a value such that the Derivative block can generate answers with adequate accuracy. To determine this value, you might need to repeatedly run the simulation using different solver settings.

When the input to this block is a discrete signal, the continuous derivative of the input exhibits an impulse when the value of the input changes. Otherwise, it is 0. Alternatively, you can define the discrete derivative of a discrete signal using the difference of the last two values of the signal, as follows:

$$y(k) = \frac{1}{\Delta t}(u(k) - u(k - 1))$$

Taking the  $z$ -transform of this equation results in:

$$\frac{Y(z)}{u(z)} = \frac{1 - z^{-1}}{\Delta t} = \frac{z - 1}{\Delta t \cdot z}$$

The **Discrete Derivative** block models this behavior. Use this block instead of the Derivative block to approximate the discrete-time derivative of a discrete signal.

## Improved Linearization with Transfer Fcn Blocks

The Laplace domain transfer function for the operation of differentiation is:

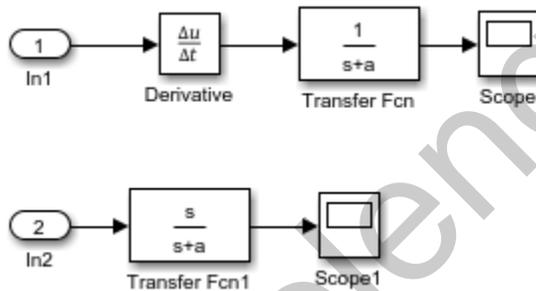

$$Y(s)/X(s) = s$$

This equation is not a proper transfer function, nor does it have a state-space representation. As such, the Simulink software linearizes this block as an effective gain of 0 unless you explicitly specify that a proper first-order transfer function should be used to approximate the linear behavior of this block (see “Coefficient  $c$  in the transfer function approximation  $s/(c*s + 1)$  used for linearization” on page 1-329).

To improve linearization, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, try using a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

For example, you can replace the first set of blocks in this figure with the blocks below them.

## Data Type Support

The Derivative block accepts and outputs a real signal of type **double**. For more information, see “Data Types Supported by Simulink”.

## Parameters

### Coefficient $c$ in the transfer function approximation $s/(c*s + 1)$ used for linearization

Specify the time constant  $c$  to approximate the linearization of your system.

## Settings

**Default:** `inf`

- The exact linearization of the Derivative block is difficult, because the dynamic equation for the block is  $y = \dot{u}$ , which you cannot represent as a state-space system. However, you can approximate the linearization by adding a pole to the Derivative to create a transfer function  $s / (c * s + 1)$ . The addition of a pole filters the signal before differentiating it, which removes the effect of noise.
- The default value `inf` corresponds to a linearization of 0.

## Tips

- A best practice is to change the value of  $c$  to  $\frac{1}{f_b}$ , where  $f_b$  is the break frequency for the filter.
- **Coefficient  $c$  in the transfer function approximation  $s/(c*s+1)$  used for linearization** must be a finite positive value. This value must be nonzero.

## Command-Line Information

**Parameter:** `CoefficientInTFapproximation`

**Type:** character vector

**Value:** `'inf'`

**Default:** `'inf'`

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Deserializer1D

Convert scalar stream or smaller vectors to vector signal

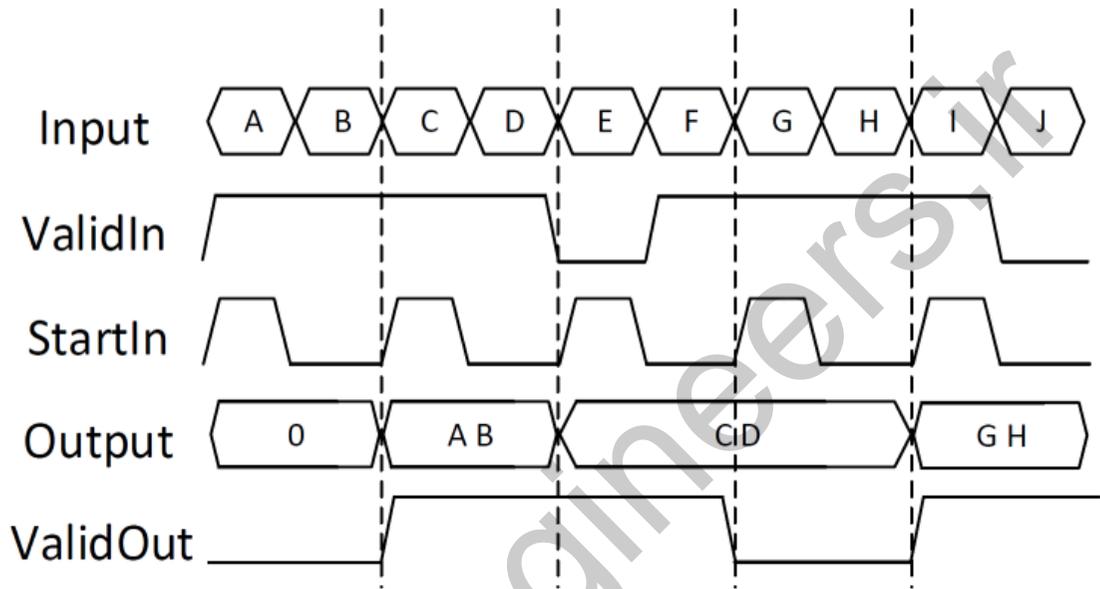

### Library

HDL Coder / HDL Operations

### Description

The Deserializer1D block buffers a faster, scalar stream or vector signals into a larger, slower vector signal. The faster input signal is converted to a slower signal based on the **Ratio** and **Idle Cycle** values, the conversion changes sample time. Also, the output signal is delayed one slow signal cycle because the serialized data needs to be collected before it can be output as a vector. See the examples below for more details.

You can configure the deserialization to depend on a valid input signal ValidIn and a start signal StartIn. If the **ValidIn** and **StartIn** block parameters are both selected, data collection starts only if both ValidIn and StartIn signals are true. Consider this example:

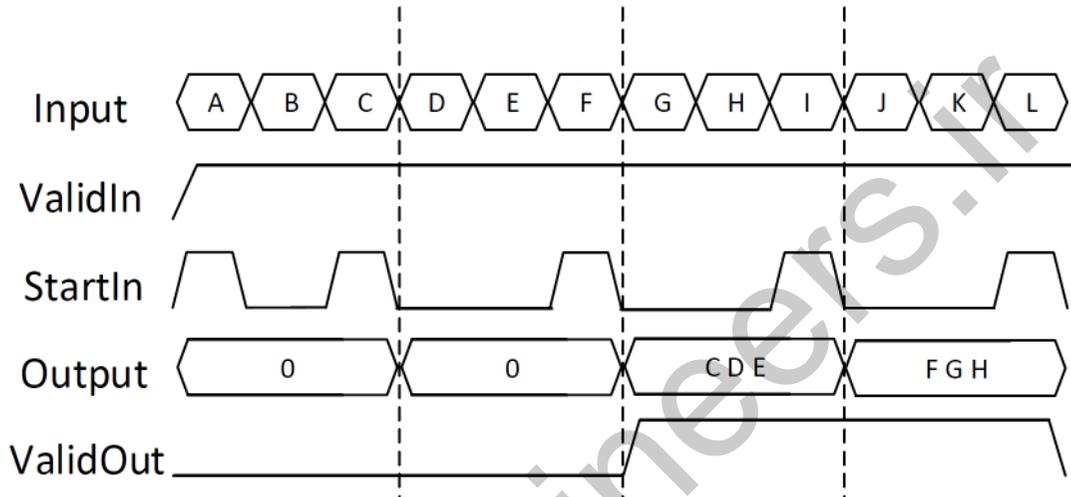

- **Ratio** is 2 and **Idle Cycles** is 0, so each output cycle is two input signals long with all data points considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both StartIn and ValidIn signals are true.
- **ValidOut** is selected.

In the first cycle, ValidIn and StartIn are true, so data collection begins for A and B. The block outputs the deserialized vector in the next valid cycle, so the AB vector is output in the next cycle. This is also true in the second cycle for C and D.

In the third cycle, starting at E, StartIn is true, but ValidIn is not. E is dropped. At F, ValidIn is true, but StartIn is not, so F is also dropped. Since it cannot collect data for E or F, Deserializer1D outputs the previous cycle vector, CD, but ValidOut changes to false.

Another scenario to consider is when the StartIn signal arrives too early. If the length between two StartIn signals is not long enough to collect a full ratio cycle, the insufficient signal data is dropped. Consider this example:

- **Ratio** is 3, so each cycle is two sections long.
- **Idle Cycles** is 0, so all data inputs are considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both StartIn and ValidIn signals are true.
- **ValidOut** is selected.

In the first cycle, ValidIn and StartIn are true, so data collection can begin for A and B. However, at C another StartIn signal arrives before three signals can be collected. Because the StartIn arrived early, A and B are dropped and no valid vector is collected during the first cycle. Therefore, the output of the second cycle is still zero. Deserialization begins at the StartIn at C, for C, D, and E. This vector is output at the next valid cycle, which is cycle 3. Similarly, deserialization starts again at the StartIn at F, and outputs the FGH vector in the fourth cycle.

You specify the block output for the first sampling period with the value of the **Initial condition** parameter.

## Parameters

### Ratio

Enter the deserialization ratio. Default is 1.

The ratio is the output vector size, divided by the input vector size. The ratio must be divisible by the input vector size.

### Idle Cycles

Enter the number of idle cycles added to the end of each serialized input. Default is 0.

The value of **Idle Cycles** affects the deserialized output rate. For example, if **Ratio** is 2 and the input signal is A, B, B, C, D, D, . . . , without idle cycles the output would be AB, BC, DD. . . . However for the same input and ratio with **Idle Cycles** set to 1, the output is AB, CD. . . . The idle cycles, B and D, are dropped.

The Deserializer1D behavior changes if **Idle Cycles** is not zero, and **ValidIn** or **StartIn** are on. The idle cycles value affects only the output rate, while **ValidIn** and **StartIn** control what input data is deserialized.

### Initial condition

Specify the initial output of the simulation. Default is 0.

### StartIn

Select to activate the StartIn port. Default is off.

### ValidIn

Select to activate the ValidIn port. Default is off.

### ValidOut

Select to activate ValidOut port. Default is off.

### Input data port dimensions (-1 for inherited)

Enter the size of the input data signal. The input size must be divisible by the ratio plus the number of idle cycles. By default, the block inherits size based on context within the model.

### Input sample time (-1 for inherited)

Enter the time interval between sample time hits or specify another appropriate sample time such as continuous. By default, the block inherits its sample time based on context within the model. For more information, see “Sample Time”.

### Input signal type

Specify the input signal type of the block as auto, real, or complex.

## Ports

S

Input signal to deserialize. Bus data types are not supported.

#### ValidIn

Indicates valid input signal. Use with the **Serializer1D** block. This port is available when you select the **ValidIn** check box.

Data type: Boolean

#### StartOut

Indicates where to start deserialization. Use with the **Serializer1D** block. This port is available when you select the **StartOut** check box.

Data type: Boolean

#### P

Deserialized output signal. Bus data types are not supported.

#### ValidOut

Indicates valid output signal. This port is available when you select the **ValidOut** check box.

Data type: Boolean

## Detect Change

Detect change in signal value

## Library

Logic and Bit Operations

## Description

The Detect Change block determines if an input does not equal its previous value.

- The output is true (equal to 1) when the input signal does not equal its previous value.
- The output is false (equal to 0) when the input signal equals its previous value.

## Data Type Support

The Detect Change block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition for the previous input  $U/z$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to boolean or uint8.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

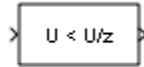

## See Also

Introduced before R2006a

## Detect Decrease

Detect decrease in signal value

## Library

Logic and Bit Operations

## Description

The Detect Decrease block determines if an input is strictly less than its previous value.

- The output is true (equal to 1) when the input signal is less than its previous value.
- The output is false (equal to 0) when the input signal is greater than or equal to its previous value.

## Data Type Support

The Detect Decrease block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition for the previous input  $U/z$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to boolean or uint8.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

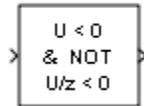

## See Also

Detect Change, Detect Fall Negative, Detect Fall Nonpositive, Detect Increase, Detect Rise Nonnegative, Detect Rise Positive

Introduced before R2006a

## Detect Fall Negative

Detect falling edge when signal value decreases to strictly negative value, and its previous value was nonnegative

## Library

Logic and Bit Operations

## Description

The Detect Fall Negative block determines if the input is less than zero, and its previous value was greater than or equal to zero.

- The output is true (equal to 1) when the input signal is less than zero, and its previous value was greater than or equal to zero.
- The output is false (equal to 0) when the input signal is greater than or equal to zero, or if the input signal is negative, its previous value was also negative.

## Data Type Support

The Detect Fall Negative block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition of the Boolean expression  $U/z < 0$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to `boolean` or `uint8`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

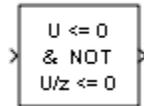

## See Also

[Detect Change](#), [Detect Decrease](#), [Detect Fall Nonpositive](#), [Detect Increase](#), [Detect Rise Nonnegative](#), [Detect Rise Positive](#)

Introduced before R2006a

## Detect Fall Nonpositive

Detect falling edge when signal value decreases to nonpositive value, and its previous value was strictly positive

### Library

Logic and Bit Operations

### Description

The Detect Fall Nonpositive block determines if the input is less than or equal to zero, and its previous value was greater than zero.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

### Data Type Support

The Detect Fall Nonpositive block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition of the Boolean expression  $U/z \leq 0$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to `boolean` or `uint8`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

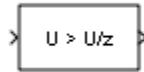

## See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Increase, Detect Rise Nonnegative, Detect Rise Positive

Introduced before R2006a

## Detect Increase

Detect increase in signal value

## Library

Logic and Bit Operations

## Description

The Detect Increase block determines if an input is strictly greater than its previous value.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

## Data Type Support

The Detect Increase block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition for the previous input  $U/z$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to boolean or uint8.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

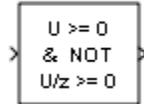

## See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Fall Nonpositive, Detect Rise Nonnegative, Detect Rise Positive

Introduced before R2006a

## Detect Rise Nonnegative

Detect rising edge when signal value increases to nonnegative value, and its previous value was strictly negative

### Library

Logic and Bit Operations

### Description

The Detect Rise Nonnegative block determines if the input is greater than or equal to zero, and its previous value was less than zero.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

### Data Type Support

The Detect Rise Nonnegative block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition of the Boolean expression  $U/z \geq 0$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to `boolean` or `uint8`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

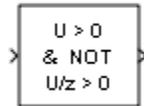

## See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Fall Nonpositive, Detect Increase, Detect Rise Positive

Introduced before R2006a

## Detect Rise Positive

Detect rising edge when signal value increases to strictly positive value, and its previous value was nonpositive

## Library

Logic and Bit Operations

## Description

The Detect Rise Positive block determines if the input is strictly positive, and its previous value was nonpositive.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

## Data Type Support

The Detect Rise Positive block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition of the Boolean expression  $U/z > 0$ .

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input  $u$ . All other input signals must be sample based.

Input Signal $u$	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output data type

Set the output data type to `boolean` or `uint8`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

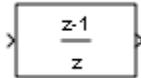

## See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Fall Nonpositive, Detect Increase, Detect Rise Nonnegative

Introduced before R2006a

## Difference

Calculate change in signal over one time step

## Library

Discrete

## Description

The Difference block outputs the current input value minus the previous input value.

## Data Type Support

The Difference block accepts signals of any numeric data type that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition for previous input

Set the initial condition for the previous input.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input **u**. All other input signals must be sample based.

Input Signal <b>u</b>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

Introduced before R2006a

# Digital Clock

Output simulation time at specified sampling interval

## Library

Sources

## Description

The Digital Clock block outputs the simulation time only at the specified sampling interval. At other times, the block holds the output at the previous value. To control the precision of this block, set the **Sample time** parameter in the block dialog box.

Use this block rather than the **Clock** block (which outputs continuous time) when you need the current simulation time within a discrete system.

## Data Type Support

The Digital Clock block outputs a real signal of type **double**. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

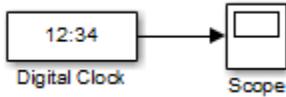

### Sample time

Specify the sampling interval. The default value is 1 second. For more information, see Specifying Sample Time in the Simulink documentation.

Do not specify a continuous sample time, either 0 or  $[0, 0]$ . Also, avoid specifying -1 (inheriting the sample time) because this block is a source.

## Examples

In the following model, the Scope block shows the output of a Digital Clock block with a **Sample time** of 0.2.

The Digital Clock block outputs the simulation time every 0.2 seconds. Otherwise, the block holds the output at the previous value.

## Characteristics

Data Types	Double
------------	--------

Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Direct Lookup Table (n-D)

Index into N-dimensional table to retrieve element, column, or 2-D matrix

## Library

Lookup Tables

## Description

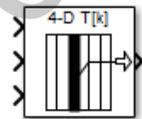

### Block Inputs and Outputs

The Direct Lookup Table (n-D) block uses inputs as zero-based indices into an  $n$ -dimensional table. The number of inputs varies with the shape of the output: an element, column, or 2-D matrix.

You define a set of output values as the **Table data** parameter. The first input specifies the zero-based index to the table dimension that is *one higher* than the output dimensionality. The next input specifies the zero-based index to the next table dimension, and so on.

Output Shape	Output Dimensionality	Table Dimension That Maps to the First Input
Element	0	1
Column	1	2
Matrix	2	3

Suppose that you want to select a column of values from a 4-D table:

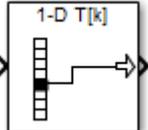

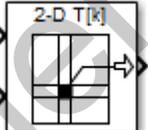

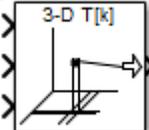

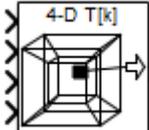

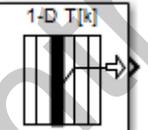

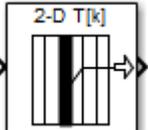

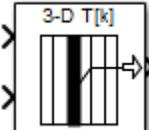

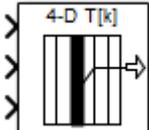

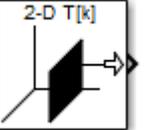

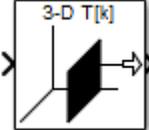

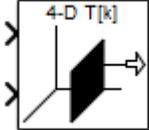

The following mapping of block input port to table dimension applies:

This input port...	Is the index for this table dimension...
1	2
2	3
3	4

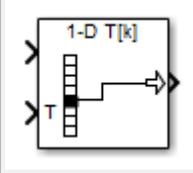

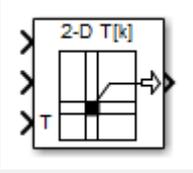

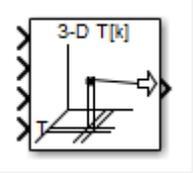

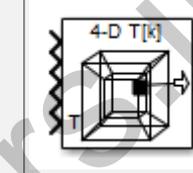

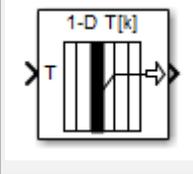

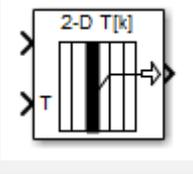

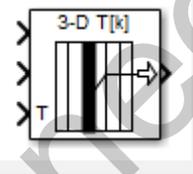

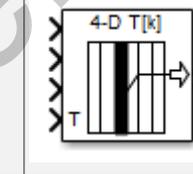

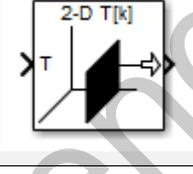

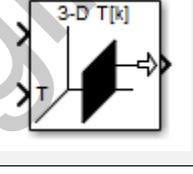

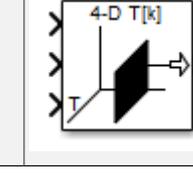

## Changes in Block Icon Appearance

Depending on parameters you set, the block icon changes appearance. For table dimensions higher than 4, the icon matches the 4-D version but shows the exact number of dimensions in the top text.

When you use the **Table data** parameter, you see the following icons:

Object That Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Column				
2-D Matrix	Not applicable			

When you use the table input port, you see the following icons:

Object That Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Column				
2-D Matrix	Not applicable			

## Data Type Support

The Direct Lookup Table (n-D) block accepts input signals of different data types.

Type of Input Port	Data Types Supported
Index port	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Boolean</li> <li>Enumerated data types</li> </ul>
Table port (with the label T)	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed point</li> <li>Boolean</li> </ul>

Type of Input Port	Data Types Supported
	<ul style="list-style-type: none"> <li>Enumerated data types</li> </ul>

The output data type is the same as the table data type. Inputs for indexing must be real, but table data can be complex.

When the table data is...	The block inherits the output type from...
Not an input	The <b>Table data type</b> parameter
An input	The table input port

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Main tab” on page 1-368
- “Table Attributes tab” on page 1-370

### Main tab

#### Number of table dimensions

Specify the number of dimensions that the **Table data** parameter must have. This value determines the number of independent variables for the table and the number of inputs to the block.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field.  The maximum number of table dimensions that this block supports is 30.

#### Inputs select this object from table

Specify whether the output data is a single element, a column, or a 2-D matrix. The number of input ports for indexing depends on your selection.

Selection	Number of Input Ports for Indexing
Element	Number of table dimensions
Column	Number of table dimensions – 1
2-D Matrix	Number of table dimensions – 2

This numbering matches MATLAB indexing. For example, if you have a 4-D table of data, follow these guidelines:

To access...	Specify...	As in...
An element	Four indices	array(1,2,3,4)
A column	Three indices	array(:,2,3,4)
A 2-D matrix	Two indices	array(:, :, 3,4)

### Make table an input

Select this check box to force the Direct Lookup Table (n-D) block to ignore the **Table data** parameter. Instead, a new input port appears with T next to it. Use this port to input table data.

### Table data

Specify the table of output values. The matrix size must match the dimensions of the **Number of table dimensions** parameter. The **Table data** field is available only if you clear the **Make table an input** check box.

---

**Tip:** During block diagram editing, you can leave the **Table data** field empty. But for simulation, you must match the number of dimensions in **Table data** to the **Number of table dimensions**. For details on how to construct multidimensional MATLAB arrays, see “Multidimensional Arrays” (MATLAB) in the MATLAB documentation.

---

Click **Edit** to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

### Diagnostic for out-of-range input

Specify whether to show a warning or error when an index is out of range with respect to the table dimension. Options include:

- **None** — Simulink software takes no action.
- **Warning** — Simulink software displays a warning and continues the simulation.
- **Error** — Simulink software terminates the simulation and displays an error.

When you select **None** or **Warning**, the block clamps out-of-range indices to fit table dimensions. For example, if the specified index is 5.3 and the maximum index for that table dimension is 4, the block clamps the index to 4.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

### Table Attributes tab

---

**Note:** The parameters in the **Table Attributes** pane are not available if you select **Make table an input**. In this case, the block inherits all table attributes from the input port with the label T.

---

#### Table minimum

Specify the minimum value for table data. The default value is [ ] (unspecified).

#### Table maximum

Specify the maximum value for table data. The default value is [ ] (unspecified).

#### Table data type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Inherit from 'Table data'**
- The name of a built-in data type, for example, **single**
- The name of a data type object, for example, a **Simulink.NumericType** object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Table data type** parameter.

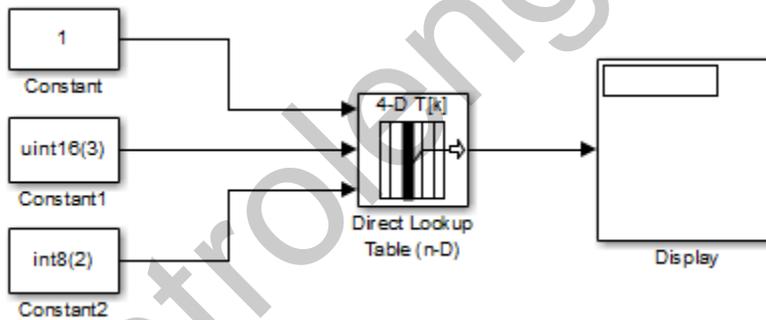

### Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

## Examples

### When Table Data Is Not an Input

Suppose that you have the following model:

The Direct Lookup Table (n-D) block parameters are:

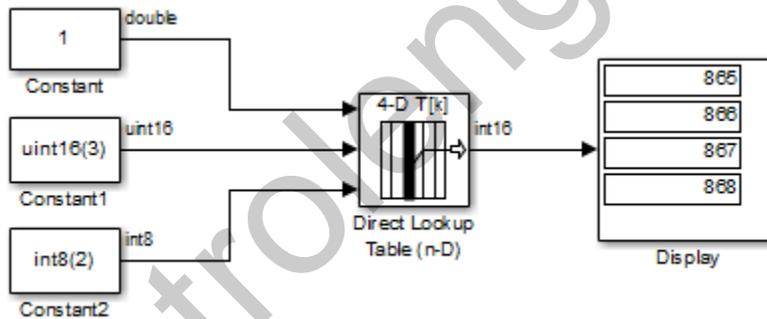

Block Parameter	Value
Number of table dimensions	4
Inputs select this object from table	Column
Make table an input	off
Table data	a

Block Parameter	Value
Diagnostic for out-of-range input	Warning
Sample time	-1
Table minimum	[ ]
Table maximum	[ ]
Table data type	int16
Lock data type settings against changes by the fixed-point tools	off

In this example, `a` is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

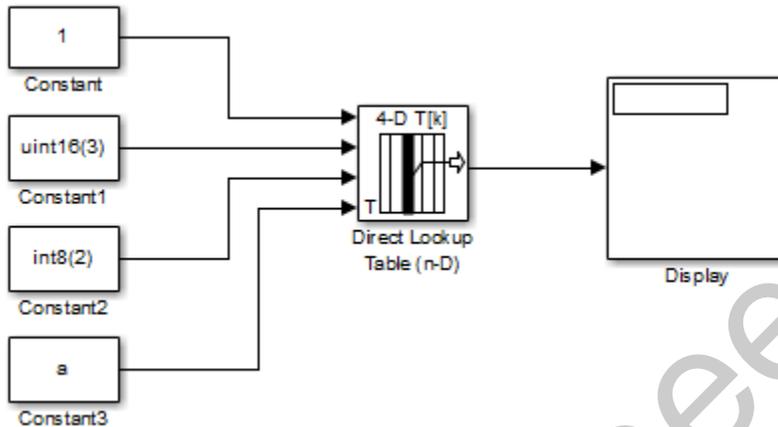

Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

```
a(:,2,4,3)
```

The output has the same data type as the table: `int16`.

### When Table Data Is an Input

Suppose that you have the following model:

The Direct Lookup Table (n-D) block parameters are:

Block Parameter	Value
Number of table dimensions	4
Inputs select this object from table	Column
Make table an input	on
Diagnostic for out-of-range input	Warning
Sample time	-1

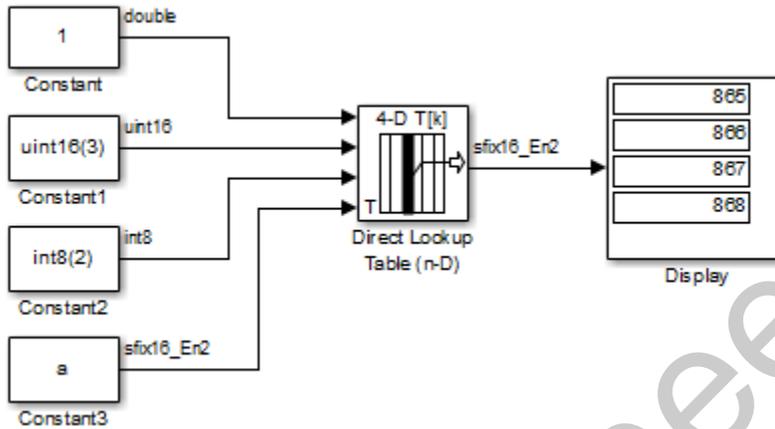

The key parameters of the Constant3 block are:

Block Parameter	Value
Constant value	a
Output data type	fixdt(1,16,2)

In this example, a is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

The Constant3 block feeds the 4-D array to the Direct Lookup Table (n-D) block, using the fixed-point data type `fixdt(1,16,2)`. Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

`a(:,2,4,3)`

The output has the same data type as the table: `fixdt(1,16,2)`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

controlengineers.ir

## Discrete Derivative

Compute discrete-time derivative

### Library

Discrete

### Description

The Discrete Derivative block computes an optionally scaled discrete time derivative as follows

$$y(t_n) = \frac{Ku(t_n)}{T_s} - \frac{Ku(t_{n-1})}{T_s}$$

where

- $u(t_n)$  and  $y(t_n)$  are the block's input and output at the current time step, respectively.
- $u(t_{n-1})$  is the block's input at the previous time step.
- $K$  is a scaling factor.
- $T_s$  is the simulation's discrete step size, which must be fixed.

---

**Note:** Do not use this block in subsystems with a non-periodic trigger (for example, non-periodic function-call subsystems). This configuration will produce inaccurate results.

---

## Data Type Support

The Discrete Derivative block supports all numeric Simulink data types, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Gain value

Scaling factor used to weight the block's input at the current time step.

### Initial condition for previous weighted input $K \cdot u / T_s$

Set the initial condition for the previous scaled input.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

---

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

## Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in Simulink User's Guide for more information.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

## Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

## Discrete Filter

Model Infinite Impulse Response (IIR) filters

## Library

Discrete

## Description

The Discrete Filter block independently filters each channel of the input signal with the specified digital IIR filter. You can specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed. The block implements static filters with fixed coefficients. You can tune the coefficients of these static filters.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify how the block treats each element of the input. You can specify treating input elements as an independent channel (sample-based processing), or treating each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal those of the input, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Use the **Numerator coefficients** parameter to specify the coefficients of the discrete filter numerator polynomial. Use the **Denominator coefficients** parameter to specify the coefficients of the denominator polynomial of the function. The **Denominator coefficients** parameter must be a vector of coefficients.

Specify the coefficients of the numerator and denominator polynomials in ascending powers of  $z^{-1}$ . The Discrete Filter block lets you use polynomials in  $z^{-1}$  (the delay operator) to represent a discrete system. This method is the one that signal processing engineers typically use. Conversely, the Discrete Transfer Fcn block lets you use polynomials in  $z$  to represent a discrete system. This method is the one that control engineers typically use. When the numerator and denominator polynomials have the same length, the two methods are identical.

### Specifying Initial States

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial states for the filter delays.

To determine the number of initial state values you must specify, and how to specify them, see the following table on Valid Initial States and Number of Delay Elements (Filter States). The **Initial states** parameter can take one of four forms as described in the following table.

#### Valid Initial States

Initial state	Examples	Description
Scalar	5  Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: $[d_1 \ d_2]$  The delay elements for all channels are $d_1$ and $d_2$ .	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay	For a 3-channel input signal and a filter with two delay elements:  $[d_1 \ d_2 \ D_1 \ D_2 \ d_1 \ d_2]$ or	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:

Initial state	Examples	Description
elements to each channel)	$\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> <li>The delay elements for channel 1 are <math>d_1</math> and <math>d_2</math>.</li> <li>The delay elements for channel 2 are <math>D_1</math> and <math>D_2</math>.</li> <li>The delay elements for channel 3 are <math>d_1</math> and <math>d_2</math>.</li> </ul>	<ul style="list-style-type: none"> <li>The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).</li> <li>The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.</li> </ul>
Empty matrix	$[ \ ]$ Each delay element for each channel is set to 0.	The empty matrix, $[ \ ]$ , is equivalent to setting the <b>Initial conditions</b> parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

#### Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements per Channel
Direct form I Direct form I transposed	<ul style="list-style-type: none"> <li>number of zeros - 1</li> <li>number of poles - 1</li> </ul>
Direct form II Direct form II transposed	$\max(\text{number of zeros, number of poles}) - 1$

The following tables describe the valid initial states for different sizes of input and different number of channels. These tables provide this information according to whether you set the **Input processing** parameter to frame based or sample based.

#### Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Column vector (<math>K</math>-by-1)</li> </ul>	1	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> </ul>

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Unoriented vector (<math>K</math>)</li> </ul>		<ul style="list-style-type: none"> <li>Row vector (1-by-<math>M</math>)</li> </ul>	
<ul style="list-style-type: none"> <li>Row vector (1-by-<math>N</math>)</li> <li>Matrix (<math>K</math>-by-<math>N</math>)</li> </ul>	$N$	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>

### Sample-Based Processing

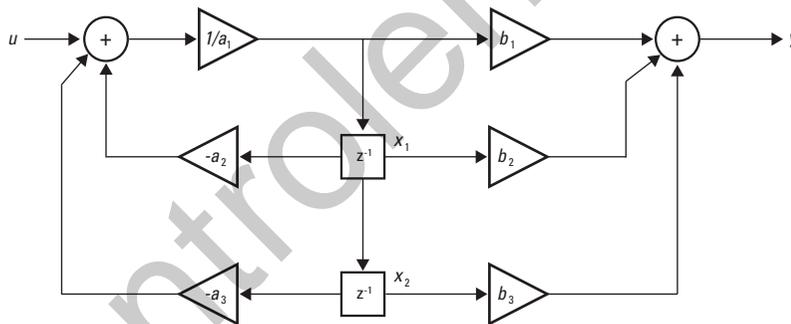

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Scalar</li> </ul>	1	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> </ul>
<ul style="list-style-type: none"> <li>Row vector (1-by-<math>N</math>)</li> <li>Column vector (<math>N</math>-by-1)</li> <li>Unoriented vector (<math>N</math>)</li> </ul>	$N$	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> </ul>
<ul style="list-style-type: none"> <li>Matrix (<math>K</math>-by-<math>N</math>)</li> </ul>	$K \times N$	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>(K \times N)</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> </ul>

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state. This unique state corresponds to a delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter,  $M = \max(\text{number of zeros, number of poles})$ .
- The matrix must have the same number of rows as the number of delay elements in the filter,  $M = \max(\text{number of zeros, number of poles})$ . The matrix must also have one column for each channel of the input signal.

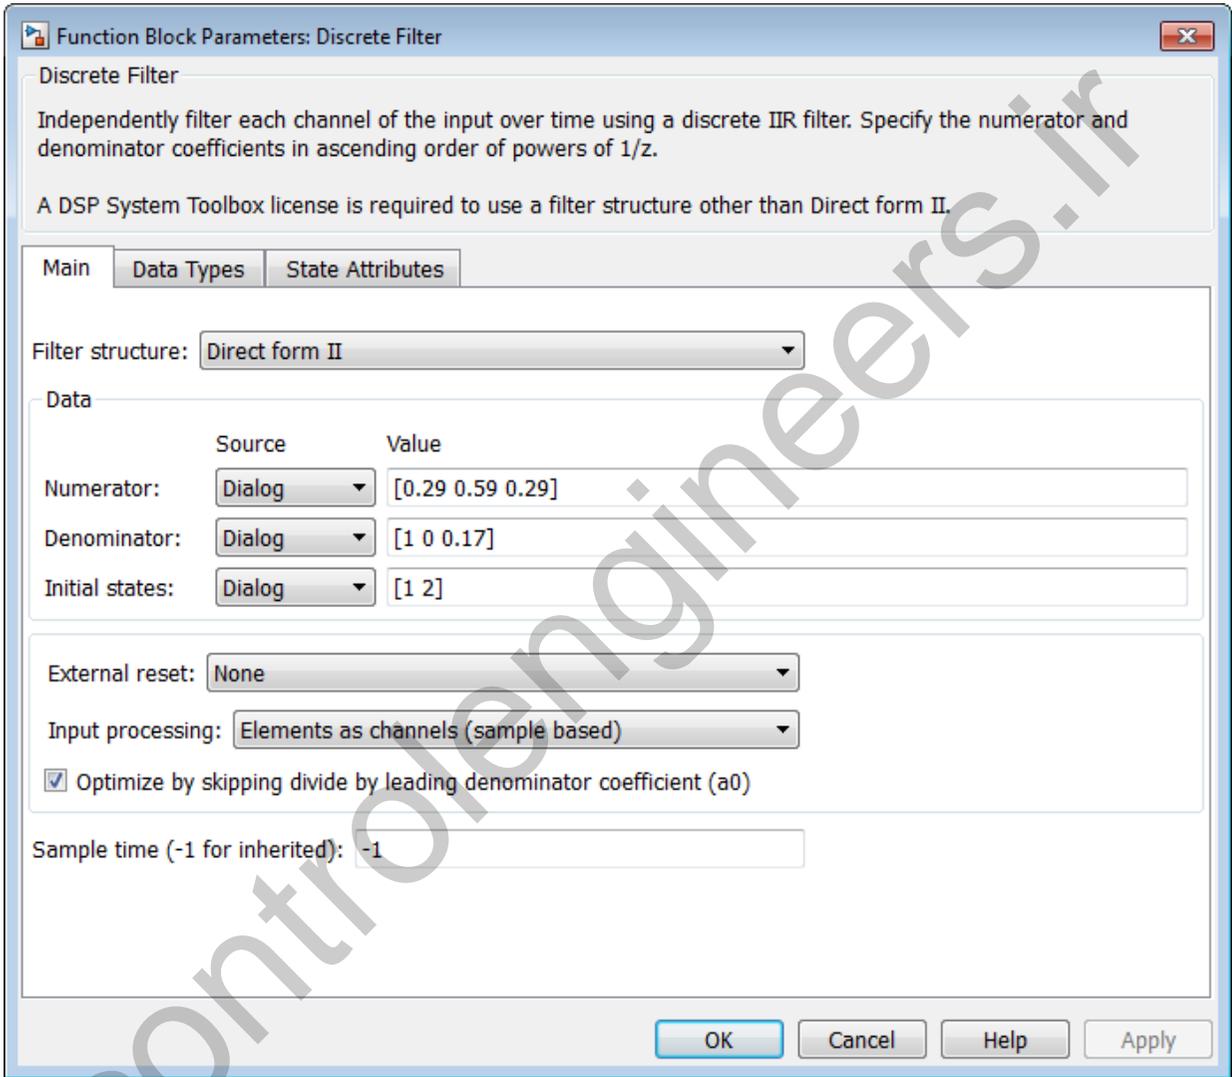

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input  $u_1$ , the first output  $y_1$  is related to the initial state  $[x_1, x_2]$  and initial input by:

$$y_1 = b_1 \left[ \frac{(u_1 - a_2 x_1 - a_3 x_2)}{a_1} \right] + b_2 x_1 + b_3 x_2$$

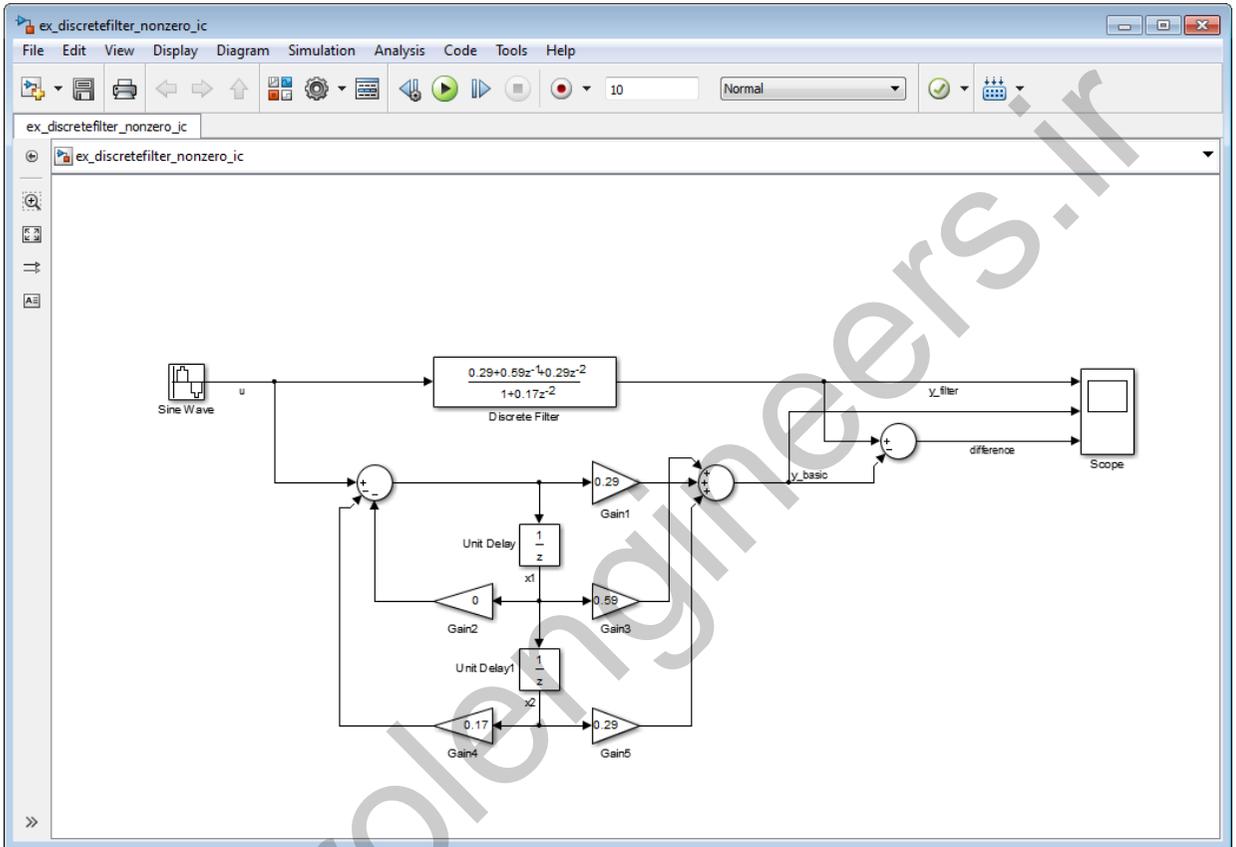

To see an example of how to set initial conditions as a vector:

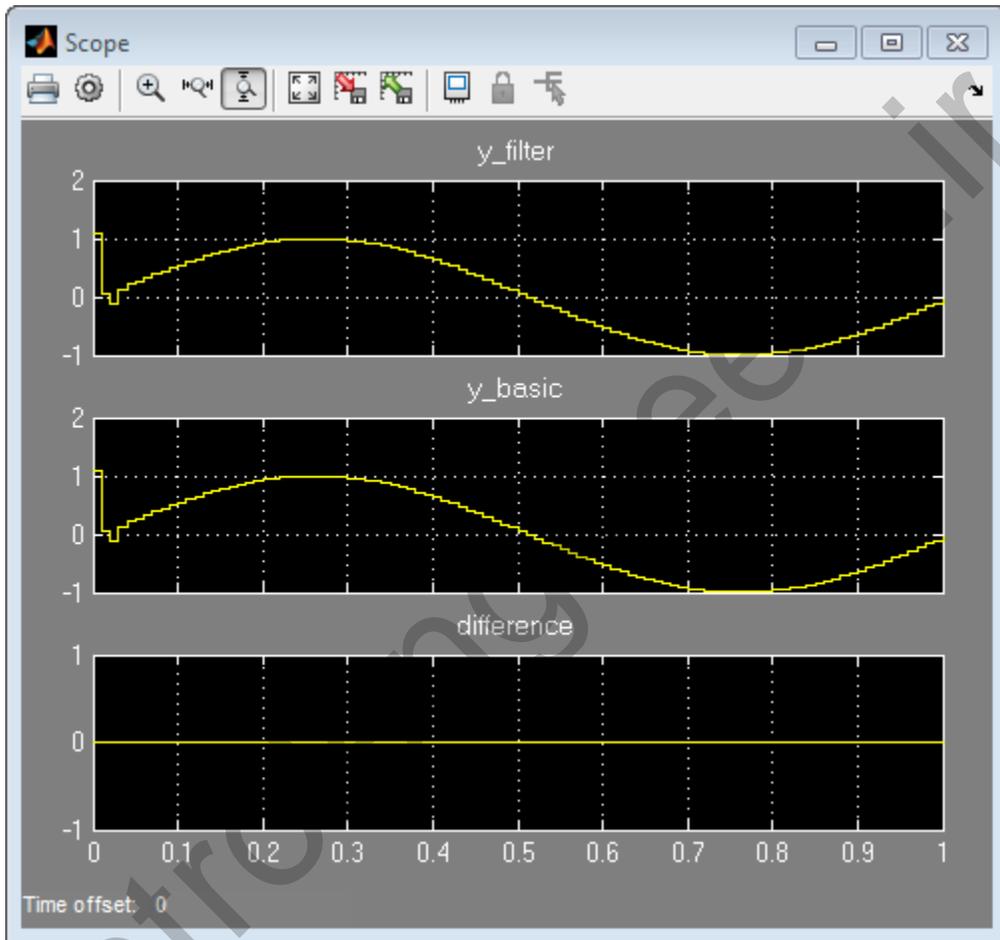

- Click on the model `ex_discretefilter_nonzero_ic`, or type it at the MATLAB command prompt.
- Double-click on the Discrete Filter block, and set the parameters. The following shows how to set the initial conditions of the Discrete Filter block to `[1 2]`.

- Simulate the model, by left-clicking the green simulation icon.

- Double-click the scope. You can see that the difference between the signal filtered by the Discrete Filter block, and the signal from the filter's building blocks, is zero.

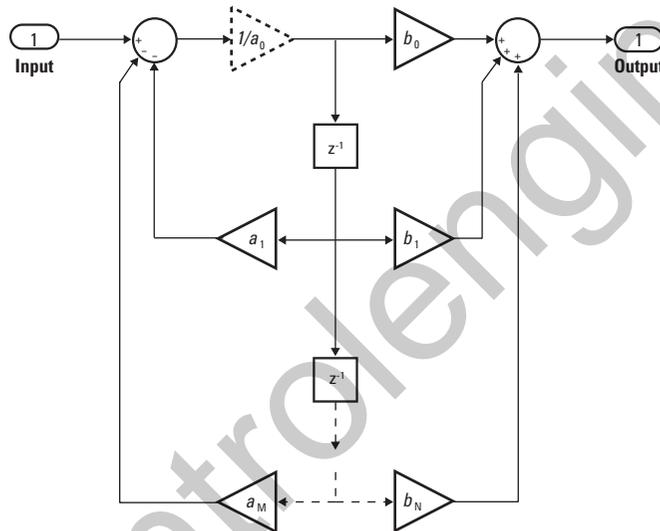

This demonstrates that you can enter the initial conditions of the Discrete Filter block as a vector of [1 2]. You can also set the initial condition of the first Unit Delay to 1 and the second Unit Delay to 2. The resulting outputs are the same.

## Data Type Support

The Discrete Filter block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

The following diagrams show the filter structure and the data types used within the Discrete Filter block for fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> <li>• when the reset signal is nonzero at the current time step</li> <li>• when the reset signal value changes from nonzero at the previous time step to zero at the current time step</li> </ul>
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

### Input processing

Specify whether the block performs sample- or frame-based processing.

- **Elements as channels (sample based)** — Process each element of the input as an independent channel.
- **Columns as channels (frame based)** — Process each column of the input as an independent channel.

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

---

### Optimize by skipping divide by leading denominator coefficient (a0)

Select when the leading denominator coefficient,  $a_0$ , equals 1. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by- $a_0$  either in simulation or in the generated code. An error occurs if  $a_0$  is not equal to one.

When you clear this check box, the block is fully tunable during simulation. It performs a divide-by- $a_0$  in both simulation and code generation.

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

### State

Specify the state data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Numerator coefficients

Specify the numerator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Numerator coefficient minimum

Specify the minimum value that a numerator coefficient can have. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### **Numerator coefficient maximum**

Specify the maximum value that a numerator coefficient can have. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### **Numerator product output**

Specify the product output data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### **Numerator accumulator**

Specify the accumulator data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Denominator coefficients

Specify the denominator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Denominator coefficient minimum

Specify the minimum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Denominator coefficient maximum

Specify the maximum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Denominator product output

Specify the product output data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Denominator accumulator

Specify the accumulator data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Output

Specify the output data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” for more information.

### Output minimum

Specify the minimum value that the block can output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Output maximum

Specify the maximum value that the block can output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit

Action	Reasons for Taking This Action	What Happens for Overflows	Example
			integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	<p>The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code>, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code>, is -126.</p>

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### State name

Use this parameter to assign a unique name to the block state. The default is ' '.

When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than **None**.

Selecting this check box disables **Code generation storage class**.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Code generation storage class

Select state storage class for code generation.

**Default:** Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

*StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name resolves
- Minimum and maximum values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
------------	--

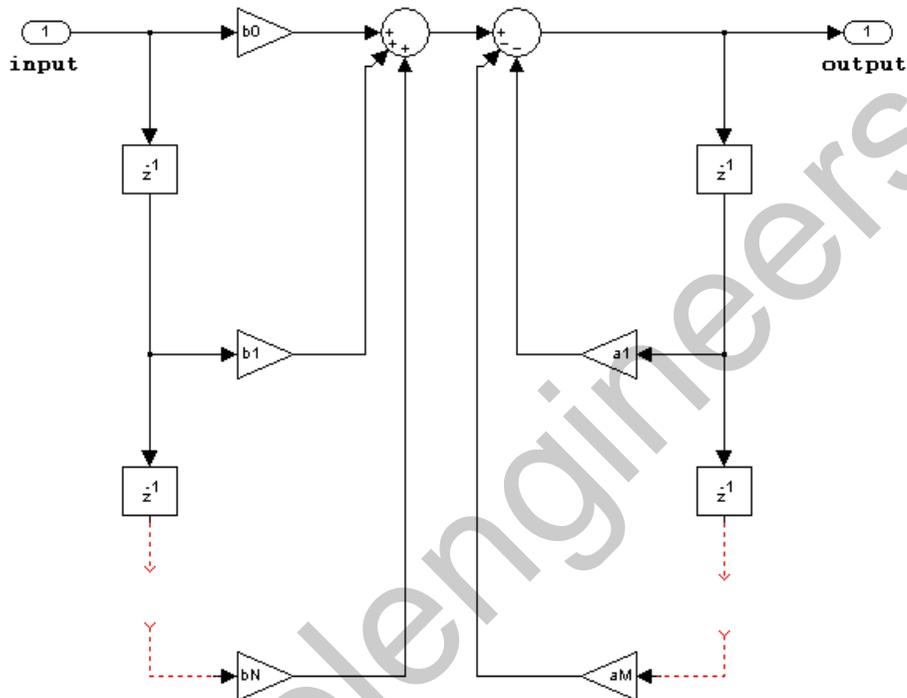

Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Only when the leading numerator coefficient does not equal zero
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog.

- “IIR direct form I” on page 1-401
- “IIR direct form I transposed” on page 1-403
- “IIR direct form II” on page 1-406
- “IIR direct form II transposed” on page 1-408

## IIR direct form I

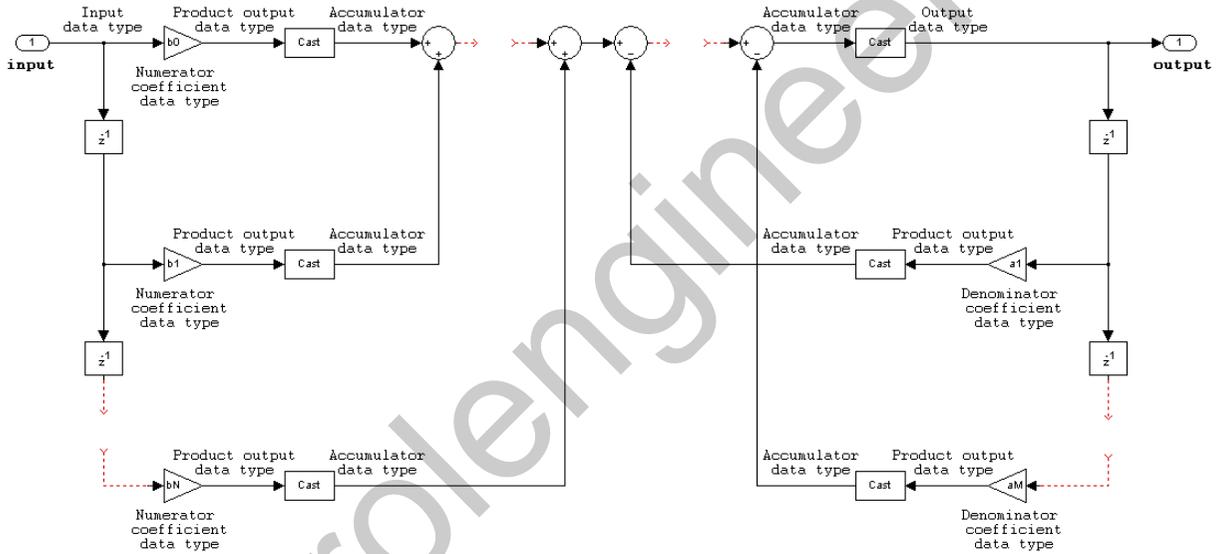

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
- When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
- When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided.

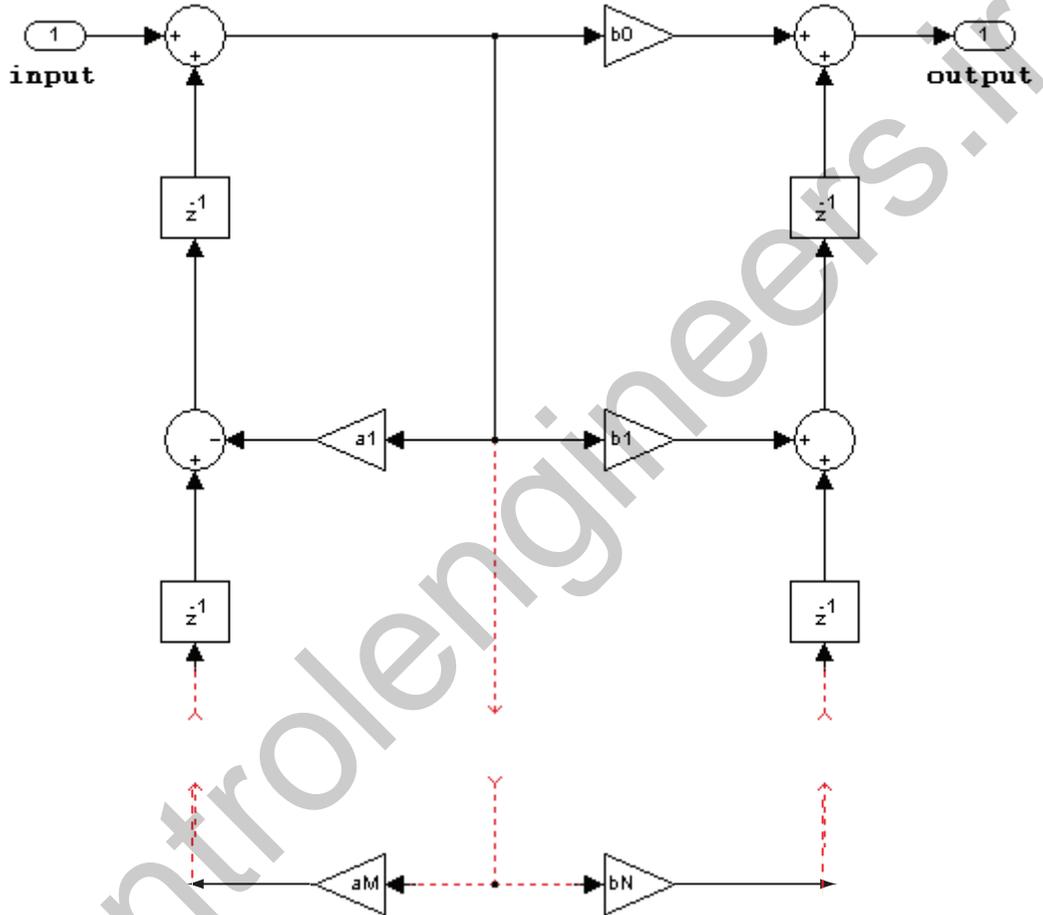

1 Blocks — Alphabetical List

The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

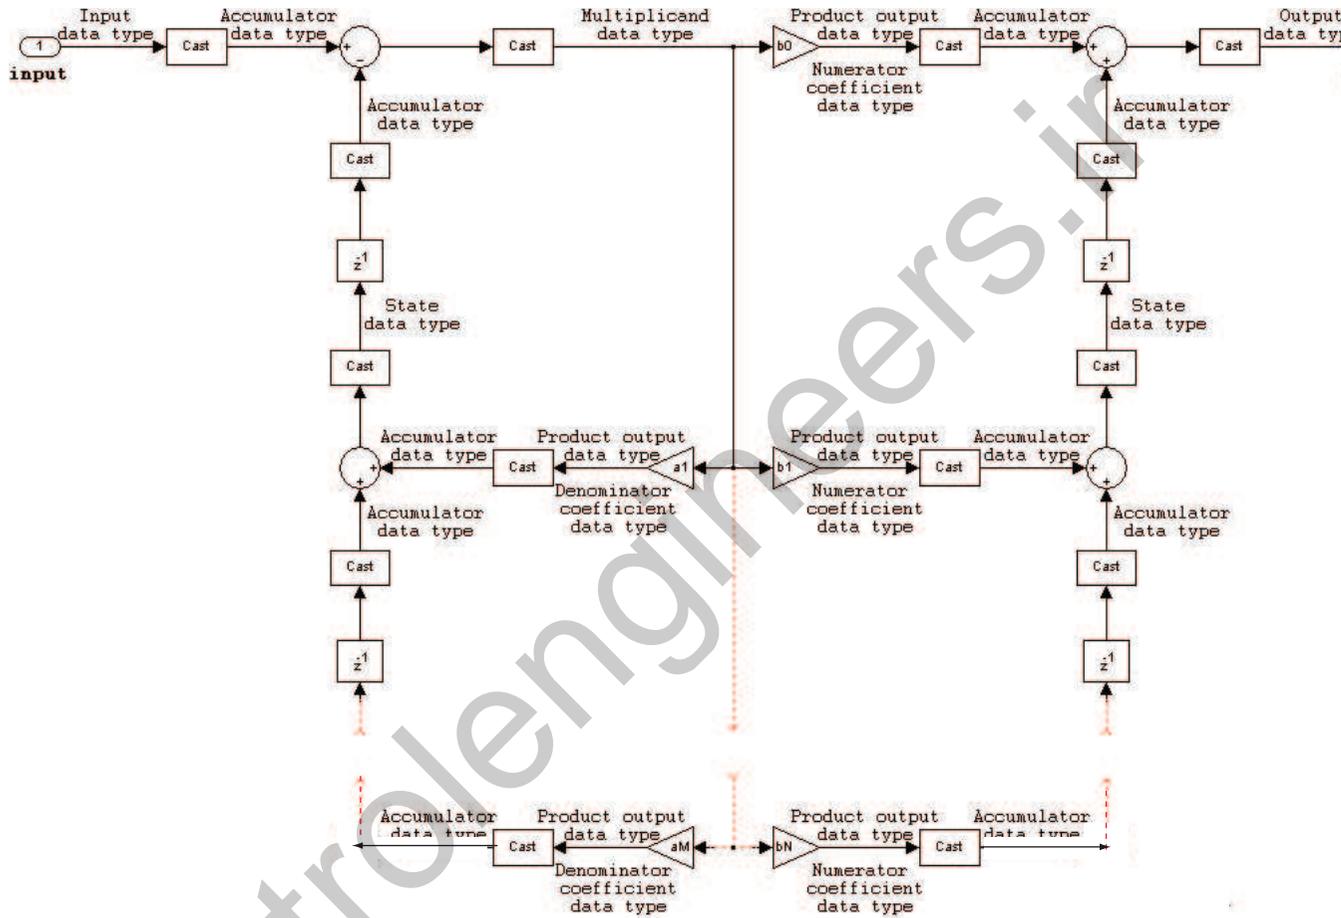

### IIR direct form I transposed

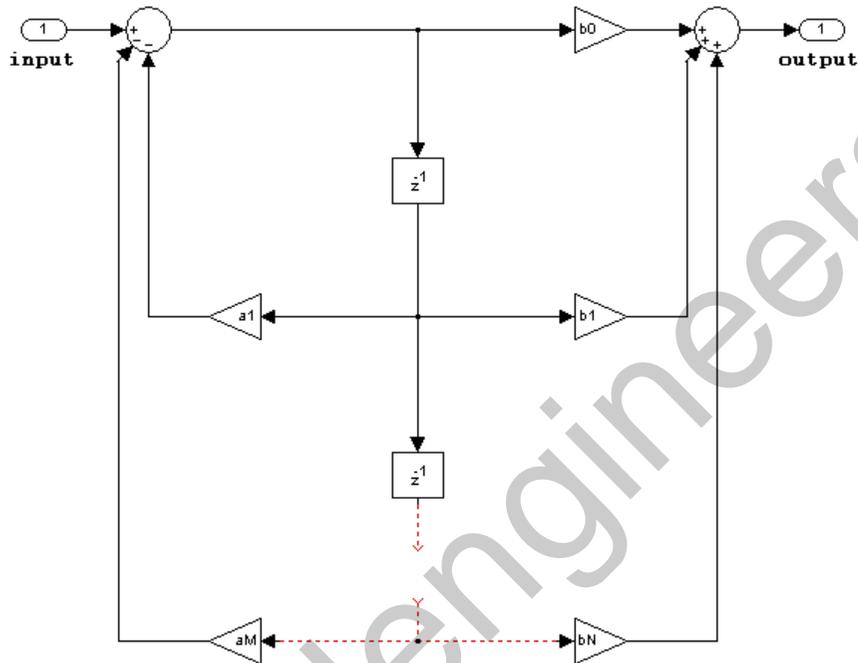

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.

- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
  - When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

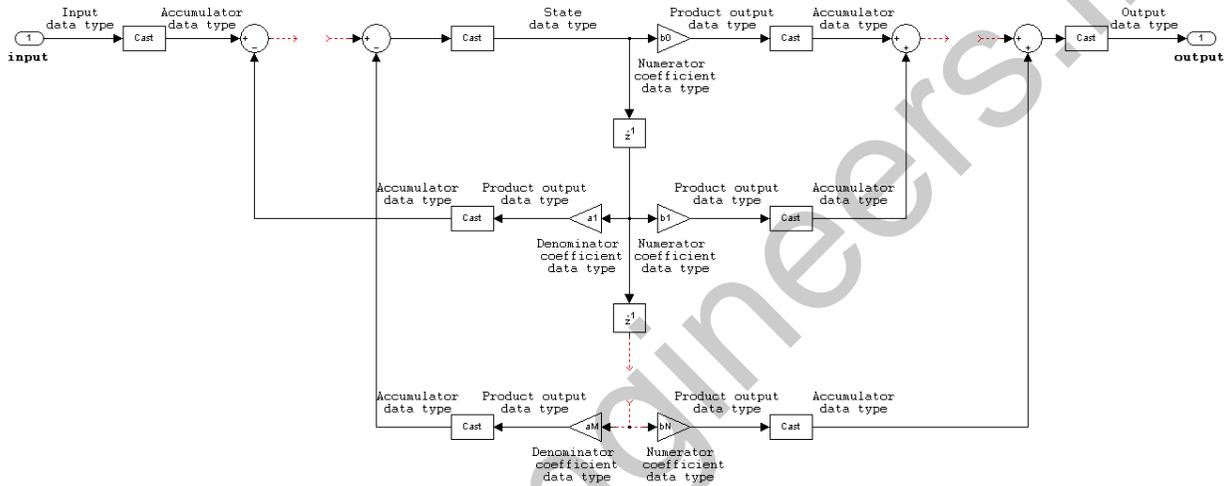

## IIR direct form II

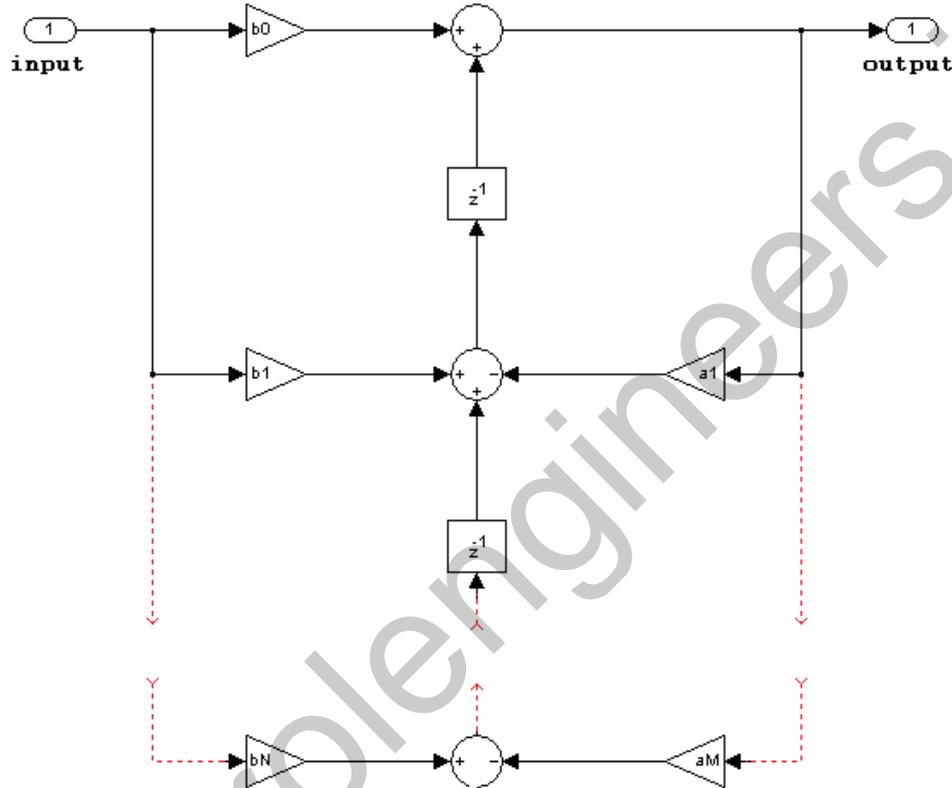

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
- When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
- When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

### IIR direct form II transposed

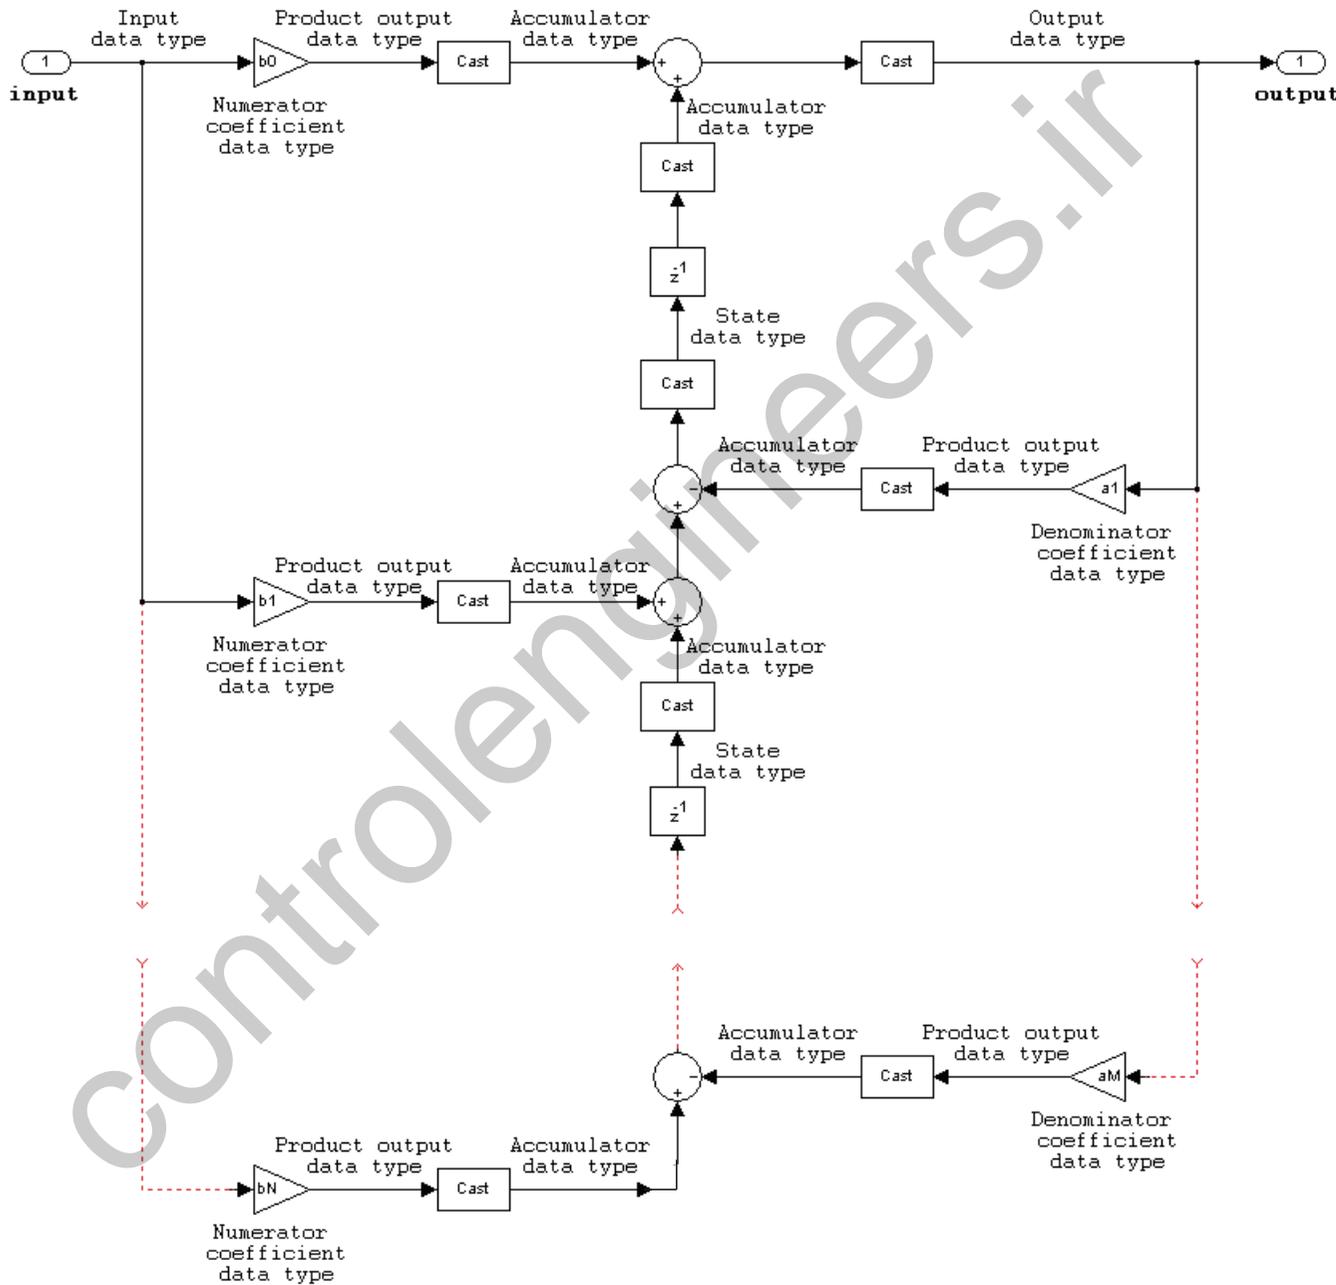

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.

- When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
- When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

## Discrete FIR Filter

Model FIR filters

### Library

Discrete

### Description

The Discrete FIR Filter block independently filters each channel of the input signal with the specified digital FIR filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal those of the input, except when you specify a matrix of filter taps for the **Coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

The outputs of this block numerically match the outputs of the DSP System Toolbox Digital Filter Design block.

This block supports the Simulink state logging feature. See “States”.

## Filter Structure Support

You can change the filter structure implemented with the Discrete FIR Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form symmetric
- Direct form antisymmetric
- Direct form transposed
- Lattice MA

You must have an available DSP System Toolbox license to run a model with any of these filter structures other than **Direct form**.

## Specifying Initial States

The Discrete FIR Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

### Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> <li>• The vector length equal the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice MA).</li> <li>• The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code></li> </ul>

Initial Condition	Description
	(#_of_reflection_coeffs for Lattice MA), and must have one column for each channel of the input signal.

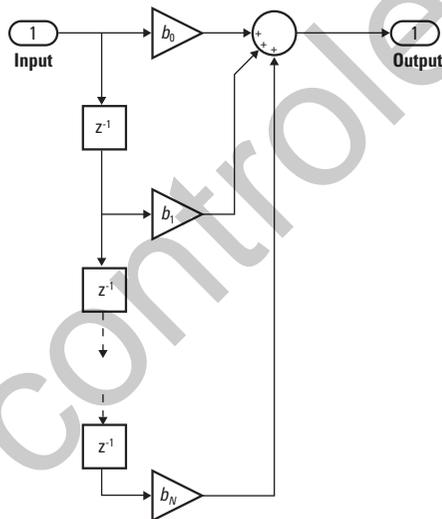

## Data Type Support

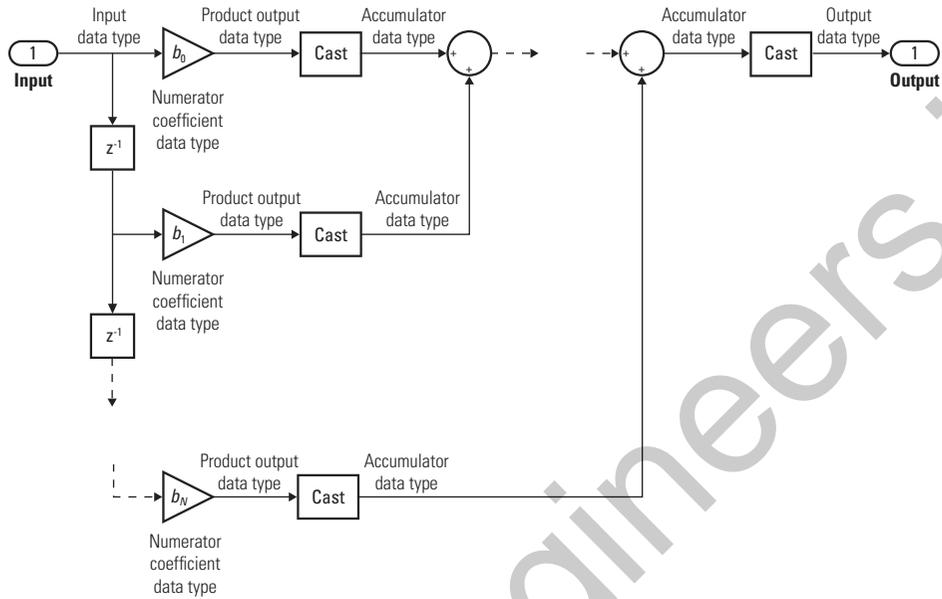

The Discrete FIR Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Discrete FIR Filter block for fixed-point signals.

### Direct Form

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

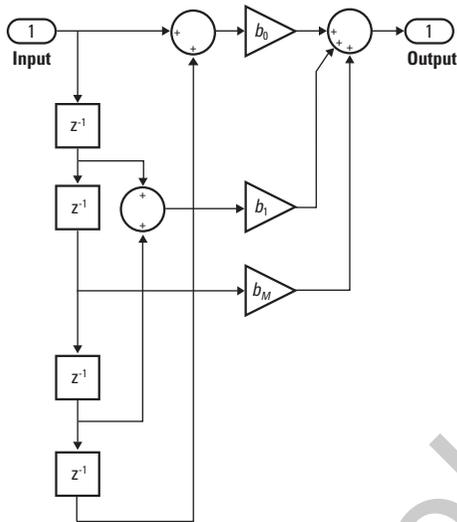

Controlengineers.ir

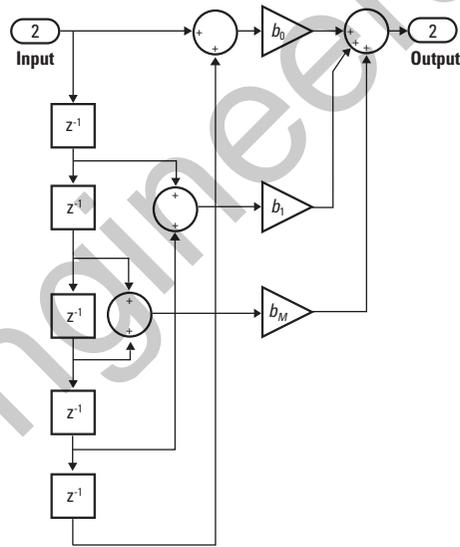

## Direct Form Symmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

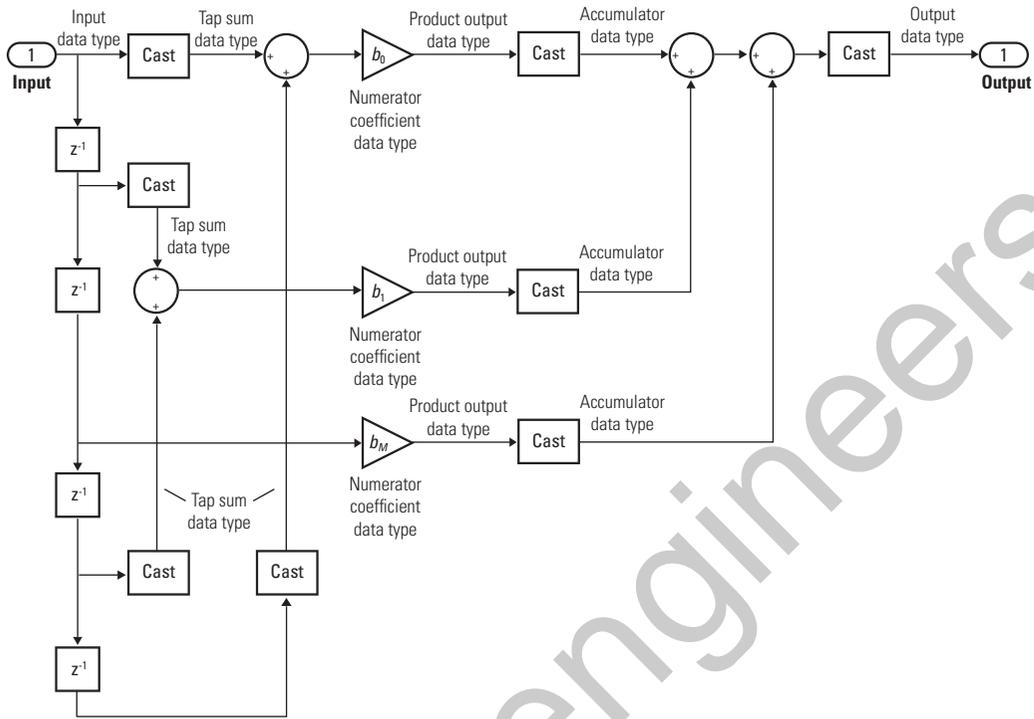

It is assumed that the filter coefficients are symmetric. The block only uses the first half of the coefficients for filtering.

## Direct Form Transposed

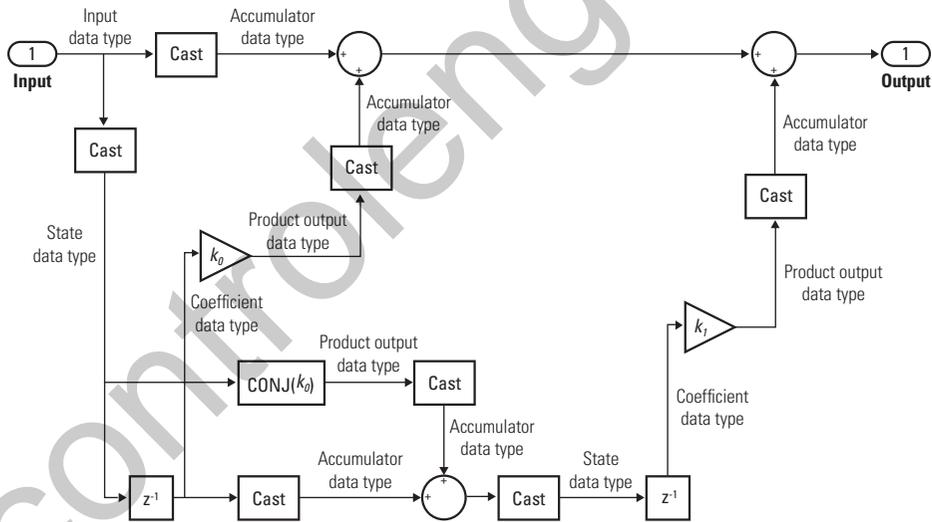

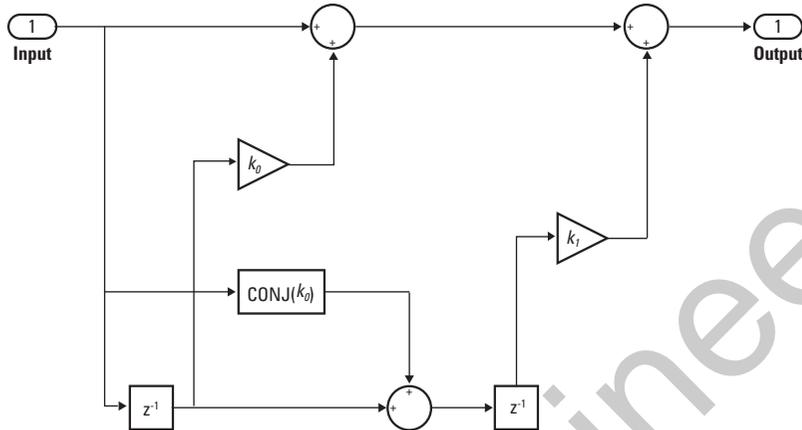

States are complex when either the inputs or the coefficients are complex.

ControlEngineers.ir

## Lattice MA

## Parameters

Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

### Filter structure

Select the filter structure you want the block to implement. You must have an available DSP System Toolbox license to run a model with a Discrete FIR Filter block that implements any filter structure other than direct form.

### Coefficients

Specify the vector coefficients of the filter's transfer function. Filter coefficients must be specified as a row vector. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps. This parameter is visible only when **Coefficient source** is set to **Dialog parameters**. For multiple filter, **Filter structure** must be **Direct form**, and the input must be a scalar.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as an independent channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as an independent channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

---

### Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-413.

### Show enable port

Select to show an enable port for this block. This port can control execution of the block. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

### External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> <li>when the reset signal is nonzero at the current time step</li> <li>when the reset signal value changes from nonzero at the previous time step to zero at the current time step</li> </ul>
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

#### Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

#### Tap sum

Specify the tap sum data type of a direct form symmetric or direct form antisymmetric filter, which is the data type the filter uses when it sums the inputs prior to multiplication by the coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Tap sum** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Same word length as input**
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Coefficients minimum

Specify the minimum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Coefficients maximum

Specify the maximum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Product output

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Inherit via internal rule**

- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Accumulator

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

### Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

#### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code.  You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced in R2008a**

## Discrete State-Space

Implement discrete state-space system

$$\begin{cases} x_{n+1} = Ax_n + Bu_n \\ y_n = Cx_n + Du_n \end{cases}$$

### Library

Discrete

### Description

#### Block Behavior for Non-Empty Matrices

The Discrete State-Space block implements the system described by

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n) \\ y(n) &= Cx(n) + Du(n), \end{aligned}$$

where  $u$  is the input,  $x$  is the state, and  $y$  is the output. The matrix coefficients must have these characteristics, as illustrated in the following diagram:

- **A** must be an n-by-n matrix, where n is the number of states.
- **B** must be an n-by-m matrix, where m is the number of inputs.
- **C** must be an r-by-n matrix, where r is the number of outputs.
- **D** must be an r-by-m matrix.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

To specify a vector or matrix of zeros for **A**, **B**, **C**, **D**, or **Initial conditions**, use the `zeros` function.

## Block Behavior for Empty Matrices

When the matrices **A**, **B**, and **C** are empty (for example, `[]`), the functionality of the block becomes  $y(n) = Du(n)$ . If the **Initial conditions** vector is also empty, the block uses an initial state vector of zeros.

## Data Type Support

The Discrete State Space block accepts and outputs a real signal of type `single` or `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### A, B, C, D

Specify the matrix coefficients, as defined in the Description section.

### Initial conditions

Specify the initial state vector. The default value is `0`. Simulink does not allow the initial states of this block to be `inf` or `NaN`.

### Sample time (–1 for inherited)

Specify the time interval between samples. See “Specify Sample Time”.

### State name

Use this parameter to assign a unique name to the block state. The default is `' '`.

When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Code generation storage class

Select state storage class for code generation.

**Default:** Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

*StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom

storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

## Characteristics

Data Types	Double   Single
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Only if $D \neq 0$

Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

# Discrete-Time Integrator

Perform discrete-time integration or accumulation of signal

## Library

Discrete

## Description

### Capabilities of the Discrete-Time Integrator Block

You can use the Discrete-Time Integrator block in place of the Integrator block to create a purely discrete system. With the Discrete-Time Integrator block, you can:

- Define initial conditions on the block dialog box or as input to the block.
- Define an input gain (K) value.
- Output the block state.
- Define upper and lower limits on the integral.
- Reset the state depending on an additional reset input.

### Output Equations

The block starts from the first time step,  $n = 0$ , with either initial output  $y(0) = IC$  or initial state  $x(0) = IC$ , depending on the **Initial condition setting** parameter value.

For a given step  $n > 0$  with simulation time  $t(n)$ , Simulink updates output  $y(n)$  as follows:

- Forward Euler method:

$$y(n) = y(n-1) + K*[t(n)-t(n-1)]*u(n-1)$$

- Backward Euler method:

$$y(n) = y(n-1) + K*[t(n)-t(n-1)]*u(n)$$

- Trapezoidal method:

$$y(n) = y(n-1) + K*[t(n)-t(n-1)]*[u(n)+u(n-1)]/2$$

Simulink automatically selects a state-space realization of these output equations depending on the block sample time, which can be explicit or triggered. When using explicit sample time,  $t(n) - t(n-1)$  reduces to the sample time  $T$  for all  $n > 0$ . For more information on these methods, see “Integration and Accumulation Methods” on page 1-438.

## Integration and Accumulation Methods

The block can integrate or accumulate using the forward Euler, backward Euler, and trapezoidal methods. Assume that  $u$  is the input,  $y$  is the output, and  $x$  is the state. For a given step  $n$ , Simulink updates  $y(n)$  and  $x(n+1)$ . In integration mode,  $T$  is the block sample time (delta  $T$  in the case of triggered sample time). In accumulation mode,  $T = 1$ . The block sample time determines when the output is computed but not the output value.  $K$  is the gain value. Values clip according to upper or lower limits.

- Forward Euler method (default), also known as forward rectangular, or left-hand approximation

For this method, the software approximates  $1/s$  as  $T/(z-1)$ . The expressions for the output of the block at step  $n$  are:

$$\begin{aligned} x(n+1) &= x(n) + K*T*u(n) \\ y(n) &= x(n) \end{aligned}$$

The block uses the following steps to compute the output:

$$\begin{aligned} \text{Step 0: } y(0) &= \text{IC (clip if necessary)} \\ x(1) &= y(0) + K*T*u(0) \end{aligned}$$

$$\begin{aligned} \text{Step 1: } y(1) &= x(1) \\ x(2) &= x(1) + K*T*u(1) \end{aligned}$$

$$\text{Step } n: \quad y(n) = x(n)$$

$$x(n+1) = x(n) + K*T*u(n) \text{ (clip if necessary)}$$

Using this method, input port 1 does not have direct feedthrough.

- Backward Euler method, also known as backward rectangular or right-hand approximation

For this method, the software approximates  $1/s$  as  $T*z / (z - 1)$ . The resulting expression for the output of the block at step  $n$  is

$$y(n) = y(n-1) + K*T*u(n).$$

Let  $x(n) = y((n) - 1)$ . The block uses these steps to compute the output.

If the parameter **Initial condition setting** is set to Output:

$$\begin{aligned} \text{Step 0: } & y(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) \end{aligned}$$

If the parameter **Initial condition setting** is set to State (most efficient):

$$\begin{aligned} \text{Step 0: } & x(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) = x(0) + K*T*u(0) \end{aligned}$$

$$\begin{aligned} \text{Step 1: } & y(1) = x(1) + K*T*u(1) \\ & x(2) = y(1) \end{aligned}$$

$$\begin{aligned} \text{Step } n: & y(n) = x(n) + K*T*u(n) \\ & x(n+1) = y(n) \end{aligned}$$

Using this method, input port 1 has direct feedthrough.

- Trapezoidal method

For this method, the software approximates  $1/s$  as  $T/2*(z+1)/(z-1)$ .

When  $T$  is fixed (equal to the sampling period), the expressions to compute the output are:

$$\begin{aligned} x(n) &= y(n-1) + K*T/2 * u(n-1) \\ y(n) &= x(n) + K*T/2*u(n) \end{aligned}$$

If the **Initial condition setting** parameter is set to Output:

$$\text{Step 0: } y(0) = \text{IC (clipped if necessary)}$$

$$x(1) = y(0) + K*T/2*u(0)$$

If the **Initial condition setting** parameter is set to State (most efficient):

$$\begin{aligned} \text{Step 0: } x(0) &= \text{IC (clipped if necessary)} \\ y(0) &= x(0) + K*T/2*u(0) \\ x(1) &= y(0) + K*T/2*u(0) \end{aligned}$$

$$\begin{aligned} \text{Step 1: } y(1) &= x(1) + K*T/2*u(1) \\ x(2) &= y(1) + K*T/2*u(1) \end{aligned}$$

$$\begin{aligned} \text{Step n: } y(n) &= x(n) + K*T/2*u(n) \\ x(n+1) &= y(n) + K*T/2*u(n) \end{aligned}$$

Here,  $x(n+1)$  is the best estimate of the next output. It is not the same as the state, in that  $x(n)$  is not equal to  $y(n)$ .

If  $T$  is variable (for example, obtained from the triggering times), the block uses these steps to compute the output.

If the **Initial condition setting** parameter is set to Output:

$$\begin{aligned} \text{Step 0: } y(0) &= \text{IC (clipped if necessary)} \\ x(1) &= y(0) \end{aligned}$$

If the **Initial condition setting** parameter is set to State (most efficient):

$$\begin{aligned} \text{Step 0: } x(0) &= \text{IC (clipped if necessary)} \\ x(1) &= y(0) = x(0) + K*T/2*u(0) \end{aligned}$$

$$\begin{aligned} \text{Step 1: } y(1) &= x(1) + T/2*(u(1) + u(0)) \\ x(2) &= y(1) \end{aligned}$$

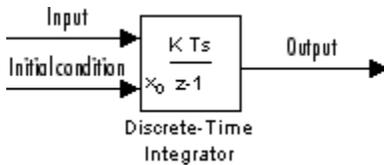

$$\begin{aligned} \text{Step n: } y(n) &= x(n) + T/2*(u(n) + u(n-1)) \\ x(n+1) &= y(n) \end{aligned}$$

Using this method, input port 1 has direct feedthrough.

## Define Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, set the **Initial condition source** parameter to **internal** and enter the value in the **Initial condition** text box.
- To provide the initial conditions from an external source, set the **Initial condition source** parameter to **external**. An additional input port appears on the block.

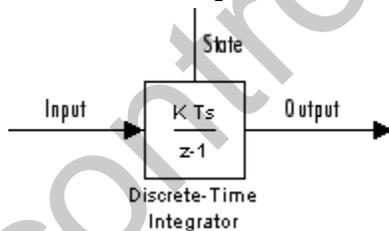

## When to Use the State Port

Use the state port instead of the output port:

- When the output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- When you want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

You can work around these problems by passing the state through the state port rather than the output port. Simulink generates the state at a slightly different time from the output, which protects your model from these problems. To output the block state, select the **Show state port** check box. The state port appears on the top of the block

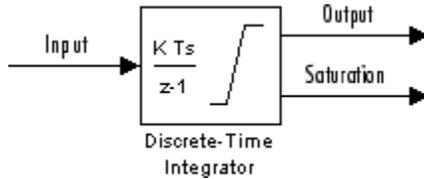

## Limit the Integral

To keep the output within certain levels, select the **Limit output** check box and enter the limits in the corresponding text box. Doing so causes the block to function as a limited integrator. When the output reaches the limits, the integral action turns off to

prevent integral windup. During a simulation, you can change the limits but you cannot change whether the output is limited. The table shows how the block determines output.

Integral	Output
Less than or equal to the <b>Lower saturation limit</b> and the input is negative	Held at the <b>Lower saturation limit</b>
Between the <b>Lower saturation limit</b> and the <b>Upper saturation limit</b>	The integral
Greater than or equal to the <b>Upper saturation limit</b> and the input is positive	Held at the <b>Upper saturation limit</b>

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A new saturation port appears below the block output port:

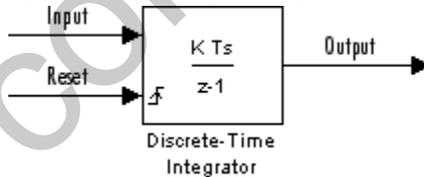

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

## Reset the State

The block can reset its state to the initial condition you specify, based on an external signal. To cause the block to reset its state, select one of the **External reset** parameter options. A reset port appears that indicates the reset trigger type:

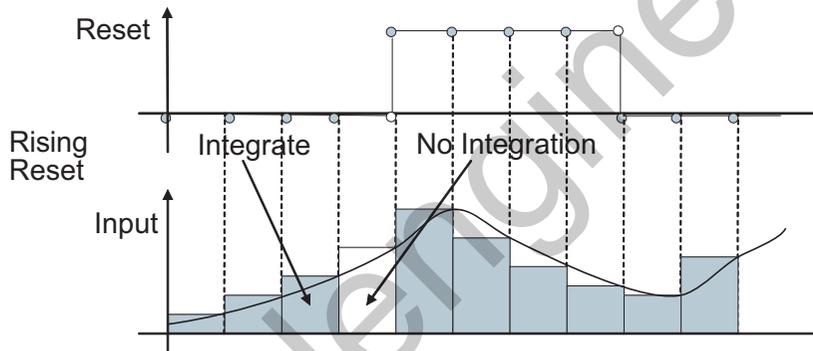

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results.

To resolve this loop, feed the output of the block state port into the reset port instead. To access the block state, select the **Show state port** check box.

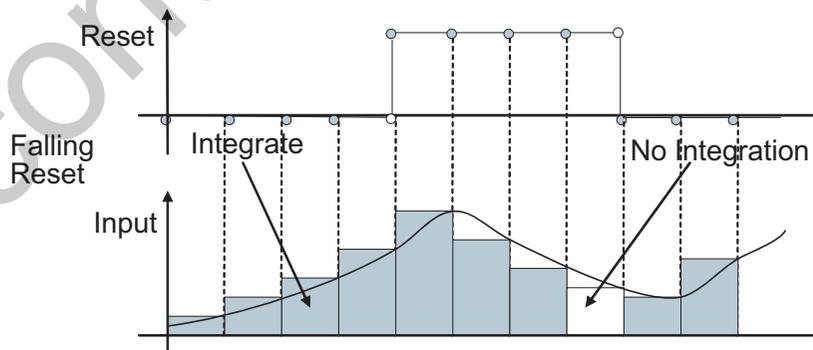

## Reset Trigger Types

The **External reset** parameter lets you determine the attribute of the reset signal that triggers the reset. The trigger options include:

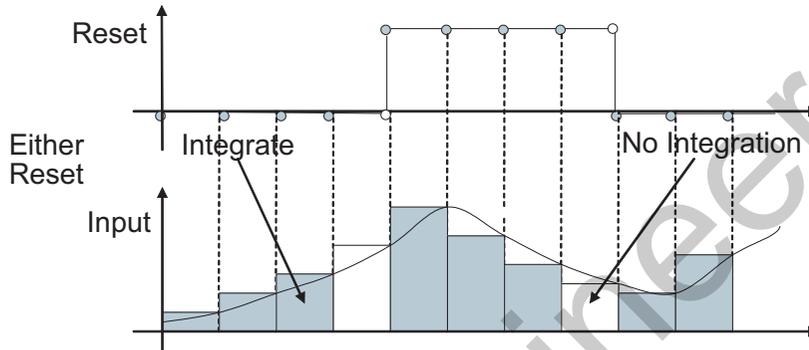

- **rising** – Resets the state when the reset signal has a rising edge. For example, this figure shows the effect that a rising reset trigger has on backward Euler integration.

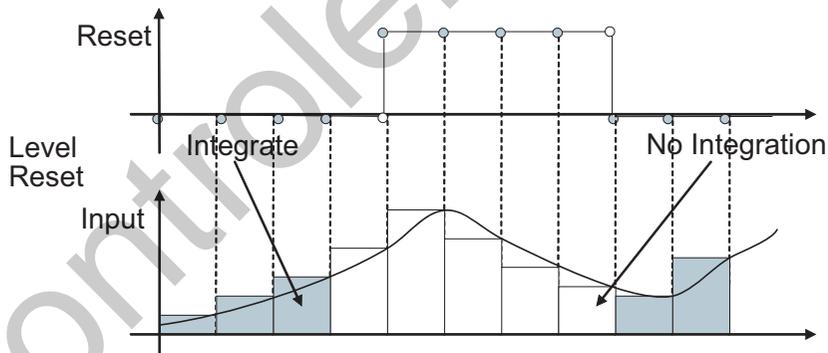

- **falling** – Resets the state when the reset signal has a falling edge. For example, this figure shows the effect that a falling reset trigger has on backward Euler integration.

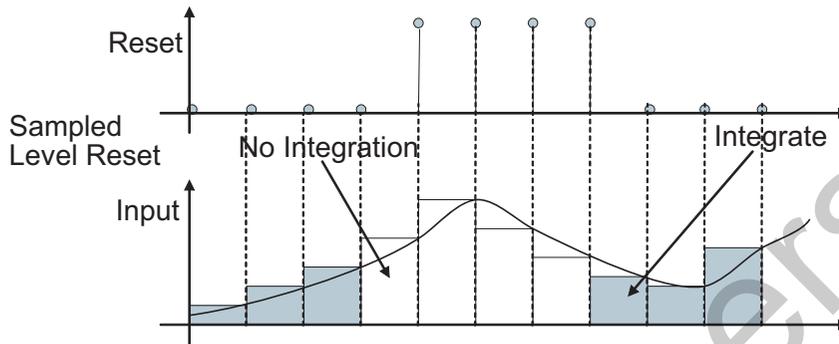

- **either** – Resets the state when the reset signal rises or falls. For example, the following figure shows the effect that an either reset trigger has on backward Euler integration.

- **level** – Resets and holds the output to the initial condition while the reset signal is nonzero. For example, this figure shows the effect that a level reset trigger has on backward Euler integration.

- **sampled level** – Resets the output to the initial condition when the reset signal is nonzero. For example, this figure shows the effect that a sampled level reset trigger has on backward Euler integration.

The **sampled level reset** option requires fewer computations, making it more efficient than the **level reset** option. However, the **sampled level reset** option can introduce a discontinuity when integration resumes.

---

**Note:** For the discrete-time integrator block, all trigger detections are based on signals with positive values. For example, a signal changing from -1 to 0 is not considered a rising edge, but a signal changing from 0 to 1 is.

---

## Behavior in Simplified Initialization Mode

Simplified initialization mode is enabled when you set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**. If you use simplified initialization mode, the behavior of the Discrete-Time Integrator block differs from classic initialization mode. The new initialization behavior is more robust and provides more consistent behavior in these cases:

- In algebraic loops
- On enable and disable
- When comparing results using triggered sample time against explicit sample time, where the block is triggered at the same rate as the explicit sample time

Simplified initialization mode enables easier conversion from Continuous-Time Integrator blocks to Discrete-Time Integrator blocks, because the initial conditions have the same meaning for both blocks.

For more information on classic and simplified initialization modes, see “Underspecified initialization detection”.

### Enable and Disable Behavior with Initial Condition Setting set to Output

When you use simplified initialization mode with **Initial condition setting** set to Output, the enable and disable behavior of the block is simplified as follows:

At disable time  $t_d$ :

$$y(t_d) = y(t_d-1)$$

At enable time  $t_e$ :

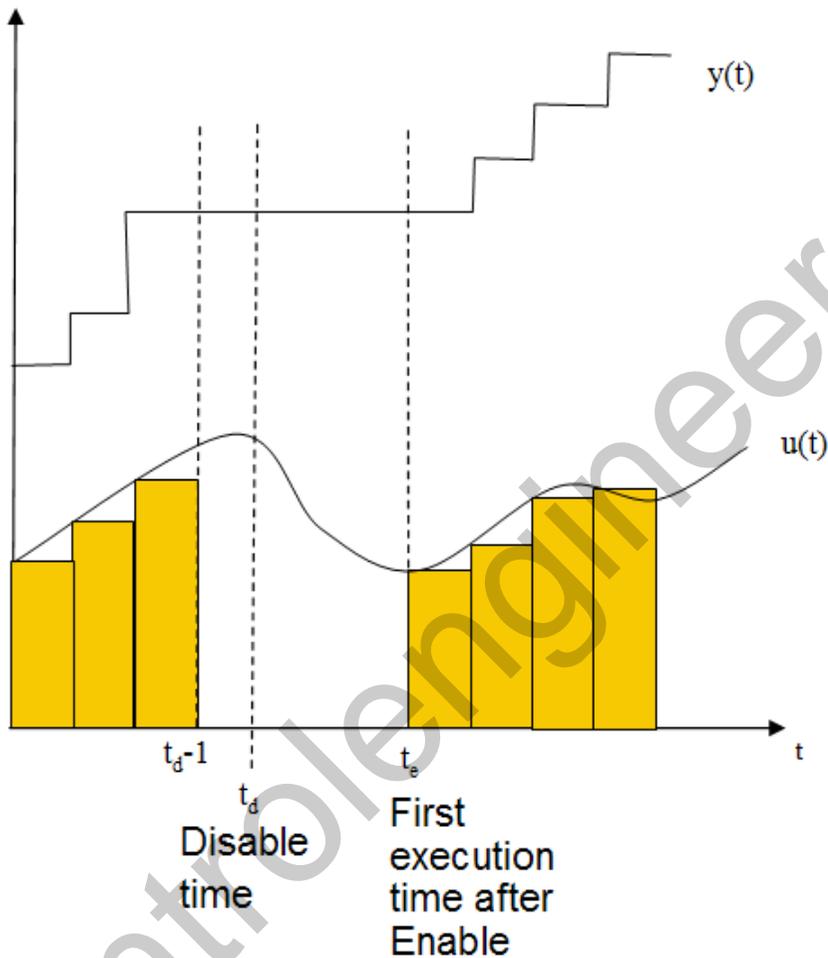

- If the parent subsystem control port has **States when enabling** set to reset:

$$y(t_e) = IC.$$

- If the parent subsystem control port has **States when enabling** set to held:

$$y(t_e) = y(t_d).$$

The following figure shows this condition.

### Iterator Subsystems

When using simplified initialization mode, you cannot place the Discrete-Time Integrator block in an Iterator Subsystem.

In simplified initialization mode, Iterator subsystems do not maintain elapsed time. Thus, if a Discrete-Time Integrator block, which needs elapsed time, is placed inside an Iterator Subsystem block, Simulink reports an error.

### Triggered Subsystems and Function-Call Subsystems

Simulink does not support model simulation when all the following conditions are true:

- A Discrete-Time Integrator block is placed within a triggered subsystem or a function-call subsystem.
- The block's **Initial condition setting** parameter is set to **State** (most efficient).
- Simplified initialization mode is enabled.

### Behavior in an Enabled Subsystem Inside a Function-Call Subsystem

Suppose that you have a function-call subsystem that contains an enabled subsystem, which contains a Discrete-Time Integrator block. The following behavior applies.

Integrator Method	Sample Time Type of Function-Call Trigger Port	Value of delta T When Function-Call Subsystem Executes for the First Time After Enabled	Reason for Behavior
Forward Euler	Triggered	$t - t_{start}$	When the function-call subsystem executes for the first time, the integrator algorithm uses $t_{start}$ as the previous simulation time.
Backward Euler and Trapezoidal	Triggered	$t - t_{previous}$	When the function-call subsystem executes for the first time, the integrator algorithm uses $t_{previous}$ as the previous simulation time.
Forward Euler, Backward Euler, and Trapezoidal	Periodic	Sample time of the function-call generator	In periodic mode, the Discrete-Time Integrator block uses sample time of the function-call generator for delta T.

## Data Type Support

The Discrete-Time Integrator block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Integrator method

Specify the integration or accumulation method.

### Settings

**Default:** Integration: Forward Euler

Integration: Forward Euler

Integrator method is Forward Euler.

Integration: Backward Euler

Integrator method is Backward Euler.

Integration: Trapezoidal

Integrator method is Trapezoidal.

Accumulation: Forward Euler

Accumulation method is Forward Euler.

Accumulation: Backward Euler

Accumulation method is Backward Euler.

Accumulation: Trapezoidal

Accumulation method is Trapezoidal.

### Command-Line Information

**Parameter:** IntegratorMethod

**Type:** character vector

**Value:** 'Integration: Forward Euler' | 'Integration: Backward Euler' | 'Integration: Trapezoidal' | 'Accumulation: Forward Euler' | 'Accumulation: Backward Euler' | 'Accumulation: Trapezoidal'

**Default:** 'Integration: Forward Euler'

## Gain value

Specify a scalar, vector, or matrix by which to multiply the integrator input. Each element of the gain must be a positive real number.

### Settings

**Default:** 1.0

- Specifying a value other than 1.0 (the default) is semantically equivalent to connecting a Gain block to the input of the integrator.
- Valid entries include:
  - `double(1.0)`
  - `single(1.0)`
  - `[1.1 2.2 3.3 4.4]`
  - `[1.1 2.2; 3.3 4.4]`
- Using this parameter to specify the input gain eliminates a multiplication operation in the generated code. However, this parameter must be nontunable to realize this benefit. If you want to tune the input gain, set this parameter to 1.0 and use an external Gain block to specify the input gain.

### Command-Line Information

**Parameter:** gainval

**Type:** character vector

**Value:** '1.0'

**Default:** '1.0'

## External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

### Settings

**Default:** none

none

Do not reset the state to initial conditions.

rising

Reset the state when the reset signal has a rising edge.

falling

Reset the state when the reset signal has a falling edge.

either

Reset the state when the reset signal rises or falls.

level

Reset and holds the output to the initial condition while the reset signal is nonzero.

sampled level

Reset the output to the initial condition when the reset signal is nonzero.

### Command-Line Information

**Parameter:** ExternalReset

**Type:** character vector

**Value:** 'none' | 'rising' | 'falling' | 'either' | 'level' | 'sampled level'

**Default:** 'none'

## Initial condition source

Get the initial conditions of the states.

### Settings

**Default:** internal

internal

Get the initial conditions of the states from the **Initial condition** parameter.

external

Get the initial conditions of the states from an external block.

### Tips

Simulink software does not allow the initial condition of this block to be inf or NaN.

### Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter.

### Command-Line Information

**Parameter:** InitialConditionSource

**Type:** character vector

**Value:** 'internal' | 'external'

**Default:** 'internal'

## Initial condition

Specify the states' initial conditions.

### Settings

**Default:** 0

**Minimum:** value of **Output minimum** parameter

**Maximum:** value of **Output maximum** parameter

### Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

### Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

### Command-Line Information

**Parameter:** InitialCondition

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

## Initial condition setting

Specify whether to apply the **Initial condition** parameter to the block state or output. This initial condition is also used as the reset value. This parameter was named **Use initial condition as initial and reset value for** in Simulink before R2014a.

### Settings

**Default:** State (most efficient)

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and **Integrator method** is set to an integration method.

Set the following initial conditions:

$$x(0) = IC$$

At reset:

$$x(n) = IC$$

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and **Integrator method** is set to an integration method.

Set the following initial conditions:

$$y(0) = IC$$

At reset:

$$y(n) = IC$$

Compatibility

This option is present to provide backward compatibility. You cannot select this option for Discrete-Time Integrator blocks in Simulink models but you can select it for Discrete-Time Integrator blocks in a library. Use this option to maintain compatibility with Simulink models created before R2014a.

Prior to R2014a, the option **State (most efficient)** was known as **State only (most efficient)**. The option **Output** was known as **State and output**. The behavior of the block with the option **Compatibility** is as follows.

- If **Configuration Parameters > All Parameters > Underspecified initialization detection** is set to **Classic**, the **Initial condition setting** parameter behaves as **State** (most efficient).
- If **Configuration Parameters > All Parameters > Underspecified initialization detection** is set to **Simplified**, the **Initial condition setting** parameter behaves as **Output**.

#### **Command-Line Information**

**Parameter:** InitialConditionSetting

**Type:** character vector

**Value:** 'State (most efficient)' | 'Output' | 'Compatibility'

**Default:** 'Output'

Controlengineers.ir

## Sample time (-1 for inherited)

Enter the discrete interval between sample time hits.

### Settings

**Default:** 1

By default, the block uses a discrete sample time of 1. To set a different sample time, enter another discrete value, such as 0.1.

See also “Specify Sample Time” in the online documentation for more information.

### Tips

- Do not specify a sample time of 0. This value specifies a continuous sample time, which the Discrete-Time Integrator block does not support.
- Do not specify a sample time of `inf` or `NaN` because these values are not discrete.
- If you specify -1 to inherit the sample time from an upstream block, verify that the upstream block uses a discrete sample time. For example, the Discrete-Time Integrator block cannot inherit a sample time of 0.

### Command-Line Information

**Parameter:** SampleTime

**Type:** character vector

**Value:** '1'

**Default:** '1'

## Limit output

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

### Settings

**Default:** Off

On

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Off

Do not limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

### Dependencies

This parameter enables **Upper saturation limit**.

This parameter enables **Lower saturation limit**.

### Command-Line Information

**Parameter:** LimitOutput

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Upper saturation limit

Specify the upper limit for the integral.

### Settings

**Default:** `inf`

**Minimum:** value of **Output minimum** parameter

**Maximum:** value of **Output maximum** parameter

### Dependencies

**Limit output** enables this parameter.

### Command-Line Information

**Parameter:** `UpperSaturationLimit`

**Type:** scalar or vector

**Value:** `'inf'`

**Default:** `'inf'`

Controlengineers.ir

## Lower saturation limit

Specify the lower limit for the integral.

### Settings

**Default:** -inf

**Minimum:** value of **Output minimum** parameter

**Maximum:** value of **Output maximum** parameter

### Dependencies

**Limit output** enables this parameter.

### Command-Line Information

**Parameter:** LowerSaturationLimit

**Type:** scalar or vector

**Value:** '-inf'

**Default:** '-inf'

Controlengineers.ir

## Show saturation port

Add a saturation output port to the block.

### Settings

**Default:** Off

On

Add a saturation output port to the block.

Off

Do not add a saturation output port to the block.

### Command-Line Information

**Parameter:** ShowSaturationPort

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

Controlengineers.ir

## Show state port

Add an output port to the block for the block's state.

### Settings

**Default:** Off

On

Add an output port to the block for the block's state.

Off

Do not add an output port to the block for the block's state.

### Command-Line Information

**Parameter:** ShowStatePort

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

Controlengineers.ir

## Ignore limit and reset when linearizing

Cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

### Settings

**Default:** Off

On

Cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Off

Do not cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

### Tips

Ignoring the limit and resetting allows you to linearize a model around an operating point. This point may cause the integrator to reset or saturate.

### Command-Line Information

**Parameter:** IgnoreLimit

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## State name

Use this parameter to assign a unique name to each state.

### Settings

**Default:** ' '

- If left blank, no name is assigned.

### Tips

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

### Dependency

This parameter enables **State name must resolve to Simulink signal object** when you click the **Apply** button.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### Command-Line Information

**Parameter:** StateIdentifier

**Type:** character vector

**Value:** ' '

**Default:** ' '

## State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

### Settings

**Default:** Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

### Dependencies

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Command-Line Information

**Parameter:** StateMustResolveToSignalObject

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

To programmatically set this parameter, use `StateSignalObject`.

For examples and more information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Settings

#### `Simulink.Signal`

Use custom storage classes from the built-in package `Simulink`.

#### `Package.Class`

Use custom storage classes from the package that defines the class that you select.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

## Code generation storage class

Select state storage class for code generation.

### Settings

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### *StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

### Dependencies

**State name** enables this parameter.

### Command-Line Information

Command-Line Information

**Parameter:** StateStorageClass

**Type:** character vector

**Value:** 'Auto' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

**Default:** 'Auto'

## Code generation storage class

Select state storage class for code generation.

### Settings

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### *StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

### Dependencies

**State name** enables this parameter.

## TypeQualifier

---

**Note:** **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

### Settings

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

### Dependency

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

### Command-Line Information

**Parameter Name:** `RTWStateStorageTypeQualifier`

**Value Type:** character vector

**Default:** ' ' (empty character vector)

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit:** Inherit via back propagation

Use data type of the driving block.

`double`

Output data type is `double`.

`single`

Output data type is `single`.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.  
`uint16`  
 Output data type is `uint16`.  
`int32`  
 Output data type is `int32`.  
`uint32`  
 Output data type is `uint32`.  
`fixdt(1,16,0)`  
 Output data type is fixed point `fixdt(1,16,0)`.  
`fixdt(1,16,2^0,0)`  
 Output data type is fixed point `fixdt(1,16,2^0,0)`.  
 <data type expression>  
 Use a data type object, for example, `Simulink.NumericType`.

#### Command-Line Information

**Parameter:** `OutDataTypeStr`

**Type:** character vector

**Value:** `'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'`

**Default:** `'Inherit: Inherit via internal rule'`

#### See Also

For more information, see “Control Signal Data Types”.

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation

##### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Fixed-point data types.

##### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

**Parameter:** OutDataTypeStr

**Type:** character vector

**Value:** 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'

**Default:** 'Inherit: Inherit via internal rule'

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > Slope and bias enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

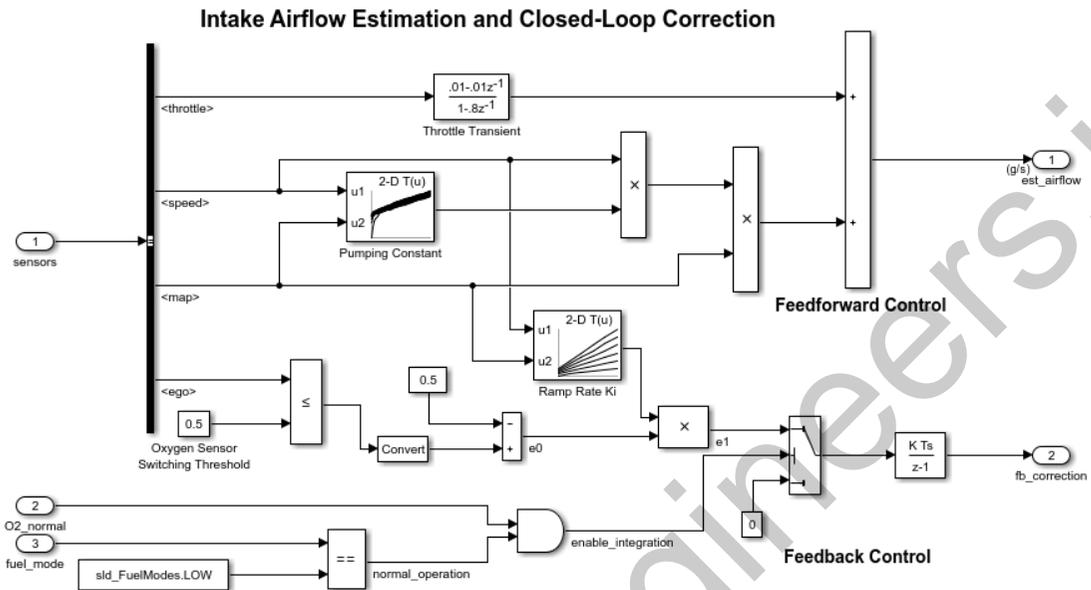

Selecting **Scaling** > Slope and bias enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Examples

The `sldemo_fuelsys` model uses a Discrete-Time Integrator block in the `fuel_rate_control/airflow_calc` subsystem. This block uses the Forward Euler integration method.

When the Switch block feeds a nonzero value into the Discrete-Time Integrator block, integration occurs. Otherwise, integration does not occur.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes, of the reset and external initial condition source ports. The input has direct feedthrough for every integration method except Forward Euler and accumulation Forward Euler.
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Discrete Transfer Fcn

Implement discrete transfer function

## Library

Discrete

## Description

The Discrete Transfer Fcn block implements the  $z$ -transform transfer function:

$$H(z) = \frac{num(z)}{den(z)} = \frac{num_0 z^m + num_1 z^{m-1} + \dots + num_m}{den_0 z^n + den_1 z^{n-1} + \dots + den_n}$$

where  $m+1$  and  $n+1$  are the number of numerator and denominator coefficients, respectively.  $num$  and  $den$  contain the coefficients of the numerator and denominator in descending powers of  $z$ .  $num$  can be a vector or matrix,  $den$  must be a vector, and you specify both as parameters on the block dialog box. The order of the denominator must be greater than or equal to the order of the numerator.

Specify the coefficients of the numerator and denominator polynomials in descending powers of  $z$ . This block lets you use polynomials in  $z$  to represent a discrete system, a method that control engineers typically use. Conversely, the Discrete Filter block lets you use polynomials in  $z^{-1}$  (the delay operator) to represent a discrete system, a method that signal processing engineers typically use. The two methods are identical when the numerator and denominator polynomials have the same length.

The Discrete Transfer Fcn block applies the  $z$ -transform transfer function to each independent channel of the input. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an individual channel

(sample-based processing), or each column of the input as an individual channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

## Specifying Initial States

Use the **Initial states** parameter to specify initial filter states. To determine the number of initial states you must specify and how to specify them, see the following tables.

### Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Column vector (<math>K</math>-by-1)</li> <li>Unoriented vector (<math>K</math>)</li> </ul>	1	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> </ul>
<ul style="list-style-type: none"> <li>Row vector (1-by-<math>N</math>)</li> <li>Matrix (<math>K</math>-by-<math>N</math>)</li> </ul>	$N$	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>

### Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Scalar</li> </ul>	1	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> </ul>
<ul style="list-style-type: none"> <li>Row vector (1-by-<math>N</math>)</li> </ul>	$N$	<ul style="list-style-type: none"> <li>Scalar</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> </ul>

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> <li>Column vector (<math>N</math>-by-1)</li> <li>Unoriented vector (<math>N</math>)</li> </ul>		<ul style="list-style-type: none"> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>N</math>)</li> </ul>	
<ul style="list-style-type: none"> <li>Matrix (<math>K</math>-by-<math>N</math>)</li> </ul>	$K \times N$	<ul style="list-style-type: none"> <li>Scalar</li> <li>Column vector (<math>M</math>-by-1)</li> <li>Row vector (1-by-<math>M</math>)</li> <li>Matrix (<math>M</math>-by-<math>(K \times N)</math>)</li> </ul>	<ul style="list-style-type: none"> <li>Scalar</li> </ul>

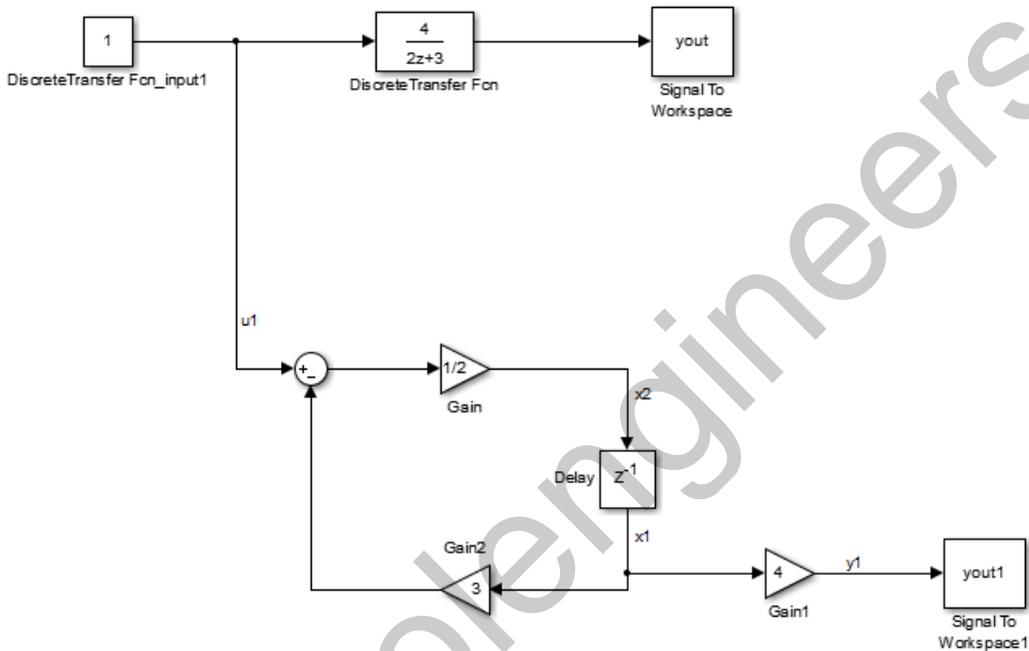

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state for a corresponding delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter,  $M = \max(\text{number of zeros, number of poles})$ .
- The matrix must have the same number of rows as the number of delay elements in the filter,  $M = \max(\text{number of zeros, number of poles})$ . The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input  $u_1$ , the first output  $y_1$  is related to the initial state  $[x_1, x_2]$  and initial input by:

$$y_1 = 4x_1$$

$$x_2 = 1/2(u_1 - 3x_1)$$

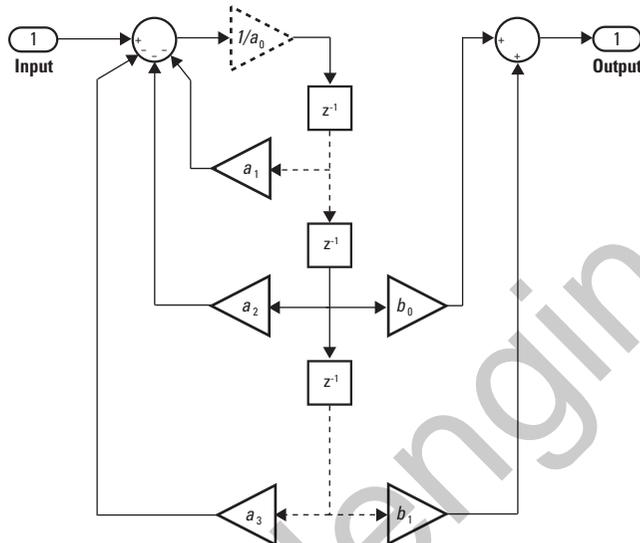

## Data Type Support

The Discrete Transfer Function block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

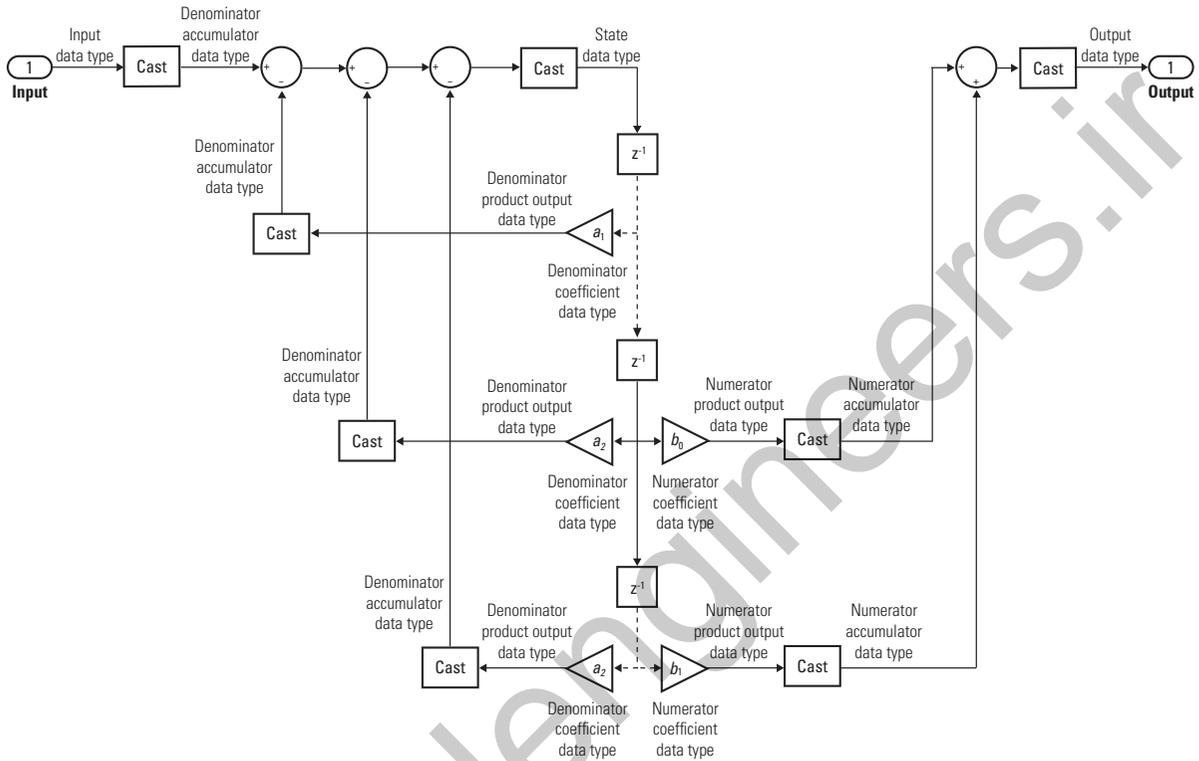

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

States are complex when either the input or the coefficients are complex.

The following diagrams show the filter structure and the data types that the block uses for floating-point and fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

## Parameters

### Numerator

Numerator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to **Dialog**. Then enter the coefficients in **Value** as descending powers of  $z$ . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

### Denominator

Denominator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to **Dialog**. Then, enter the coefficients in **Value** as descending powers of  $z$ . Use a row vector to specify the coefficients for a single denominator

polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

### Initial states

If the **Source** is **Dialog**, then, in **Value**, specify the initial states of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-490.

If the **Source** is **Input port**, then there is nothing to be specified for **Value**.

### External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> <li>• when the reset signal is nonzero at the current time step</li> <li>• when the reset signal value changes from nonzero at the previous time step to zero at the current time step</li> </ul>
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type **single**, **double**, **boolean**, or **integer**. Fixed point data types, except for **ufix1**, are not supported.

### Input processing

Specify whether the block performs sample- or frame-based processing.

- **Elements as channels (sample based)** — Process each element of the input as an independent channel.
- **Columns as channels (frame based)** — Process each column of the input as an independent channel.

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

---

### Optimize by skipping divide by leading denominator coefficient (a0)

Select when the leading denominator coefficient,  $a_0$ , equals one. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by- $a_0$  either in simulation or in the generated code. An error occurs if  $a_0$  is not equal to one.

When you clear this check box, the block is fully tunable during simulation, and performs a divide-by- $a_0$  in both simulation and code generation.

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

### State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

### Numerator coefficients

Specify the numerator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

#### **Numerator coefficient minimum**

Specify the minimum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

#### **Numerator coefficient maximum**

Specify the maximum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

#### **Numerator product output**

Specify the product output data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator product output** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Numerator accumulator

Specify the accumulator data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Denominator coefficients

Specify the denominator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Denominator coefficient minimum

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Denominator coefficient maximum

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Denominator product output

Specify the product output data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator product output** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Denominator accumulator

Specify the accumulator data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Output minimum

Specify the minimum value that the block can output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Output maximum

Specify the maximum value that the block can output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

#### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code.  You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than **None**.

Selecting this check box disables **Code generation storage class**.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage

classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Code generation storage class

Select state storage class for code generation.

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name resolves
- Minimum and maximum values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Only when the leading numerator coefficient is not equal to zero and the numerator order equals the denominator order
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Discrete Zero-Pole

Model system defined by zeros and poles of discrete transfer function

$$\frac{(z - 1)}{z(z - 0.5)}$$

## Library

Discrete

## Description

The Discrete Zero-Pole block models a discrete system defined by the zeros, poles, and gain of a  $z$ -domain transfer function. This block assumes that the transfer function has the following form:

$$H(z) = K \frac{Z(z)}{P(z)} = K \frac{(z - Z_1)(z - Z_2) \dots (z - Z_m)}{(z - P_1)(z - P_2) \dots (z - P_n)}$$

where  $Z$  represents the zeros vector,  $P$  the poles vector, and  $K$  the gain. The number of poles must be greater than or equal to the number of zeros ( $n \geq m$ ). If the poles and zeros are complex, they must be complex conjugate pairs.

The block displays the transfer function depending on how the parameters are specified. See Zero-Pole for more information.

## Data Type Support

The Discrete Zero-Pole block accepts and outputs real signals of type `double` and `single`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

Zeros

Specify the matrix of zeros. The default is [ 1 ].

### Poles

Specify the vector of poles. The default is [ 0 0.5 ].

### Gain

Specify the gain. The default is 1.

### Sample time

Specify the time interval between samples. See Specifying Sample Time in the “How Simulink Works” chapter of the Simulink documentation.

### State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Code generation storage class

Select state storage class for code generation.

#### Default: Auto

#### Auto

**Auto** is the appropriate storage class for states that you do not need to interface to external code.

#### StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

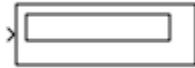

## Characteristics

Data Types	Double   Single
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes, if the number of zeros and poles are equal
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

## Display

Show value of input

## Library

Sinks

## Description

### Format Options

You control the display format using the **Format** parameter:

If you select...	The block displays...
short	A 5-digit scaled value with fixed decimal point
long	A 15-digit scaled value with fixed decimal point
short_e	A 5-digit value with a floating decimal point
long_e	A 16-digit value with a floating decimal point
bank	A value in fixed dollars and cents format (but with no \$ or commas)
hex (Stored Integer)	The stored integer value of a fixed-point input in hexadecimal format
binary (Stored Integer)	The stored integer value of a fixed-point input in binary format

If you select...	The block displays...
decimal (Stored Integer)	The stored integer value of a fixed-point input in decimal format
octal (Stored Integer)	The stored integer value of a fixed-point input in octal format

If the input to a Display block has an enumerated data type (see “Simulink Enumerations” and “Define Simulink Enumerations”):

- The block displays enumerated values, not the values of underlying integers.
- Setting **Format** to any of the **Stored Integer** settings causes an error.

## Display Abbreviations

The following abbreviations appear on the Display block to help you identify the format of the value.

When you see...	The value that appears is...
(SI)	The stored integer value
	<b>Note:</b> (SI) does not appear when the signal is of an integer data type.
hex	In hexadecimal format
bin	In binary format
oct	In octal format

## Frequency of Data Display

The amount of data that appears and the time steps at which the data appears depend on the **Decimation** block parameter and the **SampleTime** property:

- The **Decimation** parameter enables you to display data at every  $n$ th sample, where  $n$  is the decimation factor. The default decimation, 1, displays data at every time step.

---

**Note:** The Display block updates its display at the initial time, even when the **Decimation** value is greater than one.

---

- The `SampleTime` property, which you can set with `set_param`, enables you to specify a sampling interval at which to display points. This property is useful when you are using a variable-step solver where the interval between time steps is not the same. The default sample time, `-1`, causes the block to ignore the sampling interval when determining the points to display.

---

**Note:** If the block inherits a sample time of `Inf`, the **Decimation** parameter is ignored.

---

## Resizing Options

If the block input is an array, you can resize the block to show more than just the first element. You can resize the block vertically or horizontally. If the block input is a vector, the block sequentially adds display fields from left to right and top to bottom. The block displays as many values as possible. A black triangle indicates that the block is not displaying all input array elements.

The Display block shows the first 200 elements of a vector signal and the first 20 rows and 10 columns of a matrix signal.

## Floating Display

To use the block as a floating display, select the **Floating display** check box. The block input port disappears and the block displays the value of the signal on a selected line.

If you select **Floating display**:

- Turn off signal storage reuse for your model. See “Signal storage reuse” in the Simulink documentation for more information.
- Do not connect a multidimensional signal to a floating display. Otherwise, you get a simulation error because the block does not support multidimensional signals.

## Data Type Support

The Display block accepts real or complex signals of the following data types:

- Floating point

- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Format

Specify the format of the data that appears, as discussed in “Format Options” on page 1-509. The default is **short**.

### Decimation

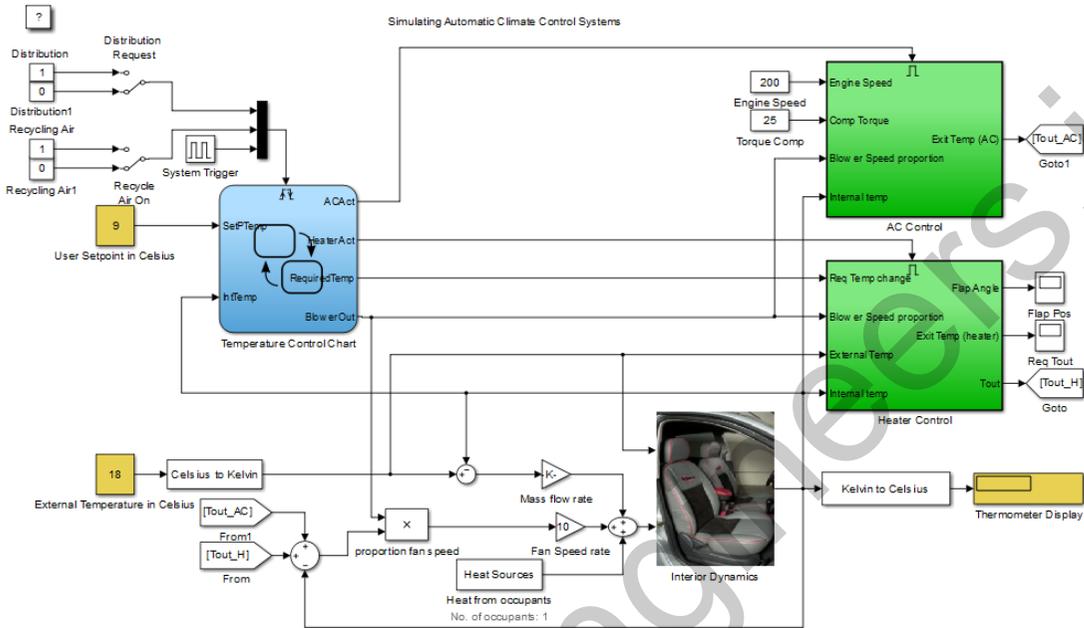

Specify how often to display data, as discussed in “Frequency of Data Display” on page 1-510. The default is 1.

### Floating display

Select to use the block as a floating display, as discussed in “Floating Display” on page 1-511.

## Examples

The `sldemo_auto_climatecontrol` model shows how you can use the Display block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Use <code>set_param</code> to specify the <code>SampleTime</code> property
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	No

## See Also

Scope

Introduced before R2006a

controlengineers.ir

## Divide

Divide one input by another

## Library

Math Operations

## Description

The Product and Product of Elements blocks are variants of the Divide block.

- For information on the Product block, see [Product](#).
- For information on the Product of Elements block, see [Product of Elements](#).

## Supported Block Operations

The Divide block outputs the result of dividing its first input by its second. The inputs can be scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The Divide block is functionally a [Product](#) block that has two block parameter values preset:

- **Multiplication:** Element-wise (.\*)
- **Number of Inputs:** \*/

Setting non-default values for either of those parameters can change a Divide block to be functionally equivalent to a [Product](#) block or a [Product of Elements](#) block. See the documentation of those two blocks for more information.

## Expected Differences Between Simulation and Code Generation

If any of the Divide block inputs contains a NaN or inf value, or if the block generates NaN or inf during execution, you might see different results when you compare the block simulation results with the generated code. This difference is due to the nonfinite NaN or inf values. In such cases, inspect your model configuration and eliminate the conditions that produce NaN or inf.

## Code Optimizations

The Simulink Coder build process provides efficient code for matrix inverse and division operations. The following summary describes the benefits and when each benefit is available:

Benefit	Small matrices (2-by-2 to 5-by-5)	Medium matrices (6-by-6 to 20-by-20)	Large matrices (larger than 20-by-20)
Faster code execution time, compared to R2011a and earlier releases	Yes	No	Yes
Reduced ROM and RAM usage, compared to R2011a and earlier releases	Yes, for real values	Yes, for real values	Yes, for real values
Reuse of variables	Yes	Yes	Yes
Dead code elimination	Yes	Yes	Yes
Constant folding	Yes	Yes	Yes
Expression folding	Yes	Yes	Yes
Consistency with MATLAB Coder results	Yes	Yes	Yes

For blocks that have three or more inputs of different dimensions, the code might include an extra buffer to store temporary variables for intermediate results.

## Parameters

### Show data type assistant

Display the **Data Type Assistant**.

#### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

### Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

#### Settings

**Default:** \* /

- **1 or \* or /**

Has one input. In element-wise mode, processes the input as described for the **Product of Elements** block. In matrix mode, if the parameter value is 1 or \*, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

- **Integer value > 1**

Has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

- **Unquoted string of two or more \* and / characters**

Has the number of inputs given by the length of the character vector. Each input that corresponds to a \* character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

### Dependency

Setting **Number of inputs** to \* and selecting `Element-wise(.*)` for **Multiplication** enables the parameter **Multiply over**.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

### Settings

**Default:** `Element-wise(.*)`

`Element-wise(.*)`

Operate in Element-wise mode.

`Matrix(*)`

Operate in Matrix mode.

### Dependency

Selecting `Element-wise(.*)` and setting **Number of inputs** to \* enable the following parameter:

- **Multiply over**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiply over

Affect multiplication on matrix input.

### Settings

**Default:** All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

### Dependencies

- Enable this parameter by selecting **Element-wise (.\*)** for **Multiplication** and setting **Number of inputs** to \* or 1 or /.
- Setting this parameter to **Specified dimension** enables the **Dimension** parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Dimension

Affect multiplication on matrix input.

### Settings

**Default:** 1

**Minimum:** 1

**Maximum:** 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

### Tips

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or \*

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

### Dependency

Enable this parameter by selecting **Specified dimension** for **Multiply over**.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

### Require all inputs to have the same data type

Require that all inputs have the same data type.

### Settings

**Default:** Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

Default: Floor

### Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

### Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

### Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Rounding” (Fixed-Point Designer).

### Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note: Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

#### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** ' [ ] '

**Default:** ' [ ] '

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit: Inherit via back propagation**

Use data type of the driving block.

**Inherit: Same as first input**

Use data type of the first input signal.

**double**

Output data type is **double**.

**single**

Output data type is **single**.

**int8**

Output data type is **int8**.

**uint8**

Output data type is **uint8**.

**int16**

Output data type is **int16**.

**uint16**

Output data type is **uint16**.

**int32**

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Control Signal Data Types”.

## Mode

Select the category of data to specify.

### Settings

**Default:** `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule` (default)
- `Inherit via back propagation`
- `Same as first input`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` (default)

- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

#### Dependency

Clicking the **Show data type assistant** button enables this parameter.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

#### See Also

See “Specify Data Types Using Data Type Assistant”.

### Data type override

Specify data type override mode for this signal.

#### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

## Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

## Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

## Settings

**Default:** Signed

**Signed**

Specify the fixed-point data as signed.

**Unsigned**

Specify the fixed-point data as unsigned.

## Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

## Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

### Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

Selecting **Binary point** enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting **Slope and bias** enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

**Dependencies**

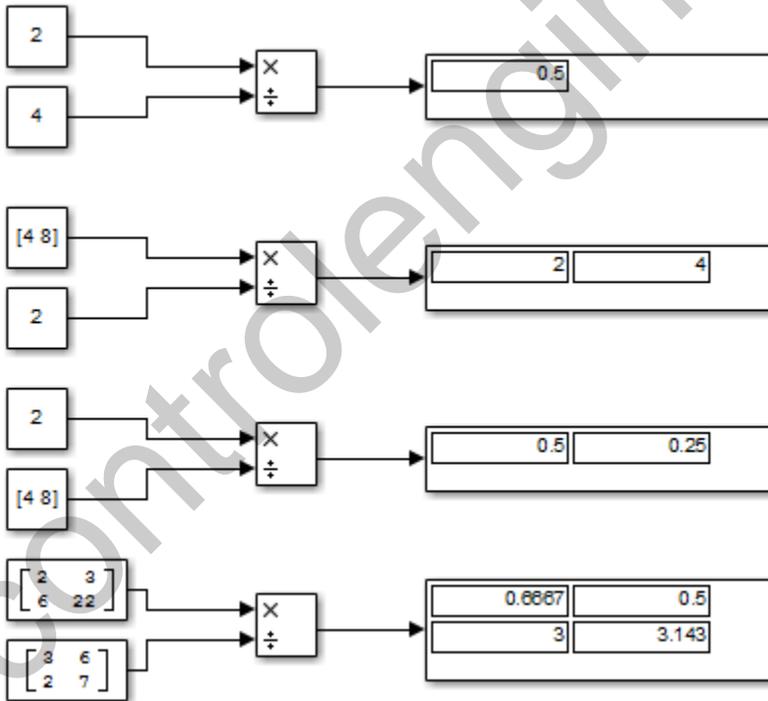

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

**See Also**

For more information, see “Specifying a Fixed-Point Data Type”.

**Examples**

The following examples show the output of the Divide block for some typical inputs using default block parameter values.

Introduced before R2006a

## DocBlock

Create text that documents model and save text with model

## Library

Model-Wide Utilities

## Description

The DocBlock allows you to create and edit text that documents a model, and save that text with the model. Double-clicking an instance of the block creates a temporary file containing the text associated with this block and opens the file in an editor. Use the editor to modify the text and save the file. Simulink software stores the contents of the saved file in the model file.

The DocBlock supports HTML, Rich Text Format (RTF), and ASCII text document types. The default editors for these different document types are

- HTML — Microsoft® Word (if available). Otherwise, the DocBlock opens HTML documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- RTF — Microsoft Word (if available). Otherwise, the DocBlock opens RTF documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- Text — The DocBlock opens text documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.

Use the `docblock` command to change the default editors.

## Data Type Support

Not applicable.

## Parameters

**Code generation template symbol** (Embedded Coder license required)

Enter a template symbol name in this field. Embedded Coder software uses this symbol to add comments to the code generated from the model. For more information, see “Add Global Comments” (Embedded Coder).

**Document type**

Select the type of document associated with the DocBlock. The options are:

- Text (the default)
- RTF
- HTML

---

**Note** If you are using a DocBlock to add comments to your code during code generation, ensure that you set the **Document Type** as Text. If you set the **Document Type** as RTF or HTML, your comments will not appear in the code.

---

## Characteristics

Data Types	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

**Introduced before R2006a**

# Dot Product

Generate dot product of two vectors

## Library

Math Operations

## Description

The Dot Product block generates the dot product of the vectors at its inputs. The scalar output,  $y$ , is equal to the MATLAB operation

$$y = \text{sum}(\text{conj}(u1) .* u2)$$

where  $u1$  and  $u2$  represent the vectors at the block's top and bottom inputs, respectively. (See "Port Location After Rotating or Flipping" in the Simulink documentation for a description of the port order for various block orientations.) The inputs can be vectors, column vectors (single-column matrices), or scalars. If both inputs are vectors or column vectors, they must be the same length. If  $u1$  and  $u2$  are both column vectors, the block outputs the equivalent of the MATLAB expression  $u1' * u2$ .

The elements of the input vectors can be real- or complex-valued signals. The signal type (complex or real) of the output depends on the signal types of the inputs.

Input 1	Input 2	Output
real	real	real
real	complex	complex
complex	real	complex
complex	complex	complex

To perform element-by-element multiplication without summing, use the Product block.

## Data Type Support

The Dot Product block accepts and outputs signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Require all inputs to have same data type

Select to require all inputs to have the same data type.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Inherit via back propagation**
- The name of a built-in data type, for example, **single**
- The name of a data type object, for example, a **Simulink.NumericType** object
- An expression that evaluates to a data type, for example, **fixdt(1,16,0)**

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

#### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

#### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

#### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	<p>The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code>, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code>, is -126.</p>

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes

Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Dual Port RAM

Dual port RAM with two output ports

### Library

HDL Coder / HDL Operations

### Description

The Dual Port RAM block models a RAM that supports simultaneous read and write operations, and has both a read data output port and write data output port. You can use this block to generate HDL code that maps to RAM in most FPGAs.

If you do not need to use the write output data, `wr_dout`, you can achieve better RAM inference with synthesis tools by using the `Simple Dual Port RAM` block.

### Read-During-Write Behavior

During a write, new data appears at the output of the write port (`wr_dout`) of the Dual Port RAM block. If a read operation occurs simultaneously at the same address as a write operation, old data appears at the read output port (`rd_dout`).

## Parameters

### Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

## Ports

The block has the following ports:

### wr\_din

Write data input. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

### wr\_addr

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

### wr\_en

Write enable.

Data type: Boolean

### rd\_addr

Read address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

### wr\_dout

Output data from write address, `wr_addr`.

### rd\_dout

Output data from read address, `rd_addr`.

Dual Rate Dual Port RAM | Simple Dual Port RAM | Single Port RAM

Introduced in R2014a

controlengineers.ir

## Dual Rate Dual Port RAM

Dual Port RAM that supports two rates

### Library

HDL Coder / HDL Operations

### Description

The Dual Rate Dual Port RAM block models a RAM that supports simultaneous read and write operations to different addresses at two clock rates. Port A of the RAM can run at one rate, and port B can run at a different rate.

In high-performance hardware applications, you can use this block to access the RAM twice per clock cycle. If you generate HDL code, this block maps to a dual-clock dual-port RAM in most FPGAs.

### Simultaneous Access

You can access different addresses from ports A and B simultaneously. You can also read the same address from ports A and B simultaneously.

However, do not access an address from one RAM port while it is being written from the other RAM port. During simulation, if you access an address from one RAM port at the

same time as you write that address from the other RAM port, the software reports an error.

## Read-During-Write Behavior

The RAM has write-first behavior. When you write to the RAM, the new write data is immediately available at the output port.

## HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

## Parameters

### Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 28. The default value is 8.

## Ports

The block has the following ports:

`din_A`

Write data input for RAM port A. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_A`

Write address for RAM port A.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we_A`

Write enable for RAM port A. Set `we_A` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`din_B`

Write data input for RAM port B. The data can be of any width, and inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_B`

Write address for RAM port B.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we_B`

Write enable for RAM port B. Set `we_B` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`dout_A`

Output data from RAM port A address, `addr_A`.

`dout_B`

Output data from RAM port B address, `addr_B`.

## Enable

Add enable port to model or system

## Library

Ports & Subsystems

## Description

Adding an Enable block to a subsystem or at the root level of a model makes it an enabled system. A subsystem can contain no more than one Enable block. An enabled system executes while the input received at the Enable port is greater than zero.

At the start of a simulation, Simulink software initializes the states of blocks inside an enabled system to their initial conditions.

If you use an enable port for a root-level model:

- For multi-rate enabled models, set the solver to single-tasking.
- If the enabled model has a fixed-step size, at least one block in that model must run at that fixed-step size rate.

The Enable block supports signal label propagation.

## Data Type Support

The Enable block accepts signals of supported Simulink numeric data types, including fixed-point data types. For more information, see “Data Types Supported by Simulink”.

## Parameters

- “States when enabling” on page 1-548
- “Propagate sizes of variable-size signals” on page 1-549
- “Show output port” on page 1-550
- “Enable zero-crossing detection” on page 1-551
- “Port dimensions” on page 1-552
- “Sample time” on page 1-553
- “Minimum” on page 1-554
- “Maximum” on page 1-555
- “Data type” on page 1-556
- “Show data type assistant” on page 1-112
- “Mode” on page 1-559
- “Interpolate data” on page 1-561

Controlengineers.ir

## States when enabling

At the instant when an enabled system is being disabled, specify what happens to the states of blocks in the enabled system.

### Settings

**Default:** held

held

Holds the states at their previous values.

reset

Resets the states to their initial conditions (zero if not defined).

### Command-Line Information

**Parameter:** StatesWhenEnabling

**Type:** character vector

**Value:** 'held' | 'reset'

**Default:** 'held'

controlengineers.ir

## Propagate sizes of variable-size signals

Specify when to propagate a variable-size signal.

### Settings

**Default:** Only when enabling

Only when enabling

Propagates variable-size signals only when reenabling the system containing the Enable Port block. When you select this option, sample time must be periodic.

During execution

Propagates variable-size signals at each time step.

### Command-Line Information

**Parameter:** PropagateVarSize

**Type:** character vector

**Value:** 'Only when enabling' | 'During execution'

**Default:** 'Only when enabling'

Controlengineers.ir

## Show output port

Select this check box to output the enabling signal.

### Settings

**Default:** On

On

Shows the Enable block output port and outputs the enabling signal. Selecting this option allows the system to process the enabling signal.

Off

Removes the output port from the Enable block.

### Command-Line Information

**Parameter:** ShowOutputPort

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Enable zero-crossing detection

Select this check box to enable zero-crossing detection.

### Settings

**Default:** On

On

Detect zero crossings.

Off

Do not detect zero crossings.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Port dimensions

Specify the dimensions of the input signal to the block.

### Settings

**Default:** 1

Valid values are:

n	Vector signal of width n accepted
[m n]	Matrix signal having m rows and n columns accepted

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Sample time

Specify the time interval between samples.

### Settings

**Default:** - 1

See “Specify Sample Time” in the online documentation for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Minimum

Specify the minimum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Data type

Specify the output data type of the external input.

### Settings

**Default:** double

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

The name of a data type object, for example Simulink.NumericType

Do not specify a bus object as the expression.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** double

Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Interpolate data

Cause the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

### Settings

**Default:** On

On

Cause the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

Off

Do not cause the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

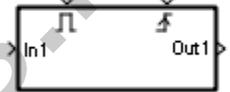

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Determined by the signal at the enable port
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

**Introduced before R2006a**

# Enabled and Triggered Subsystem

Subsystem whose execution is enabled and triggered by external input

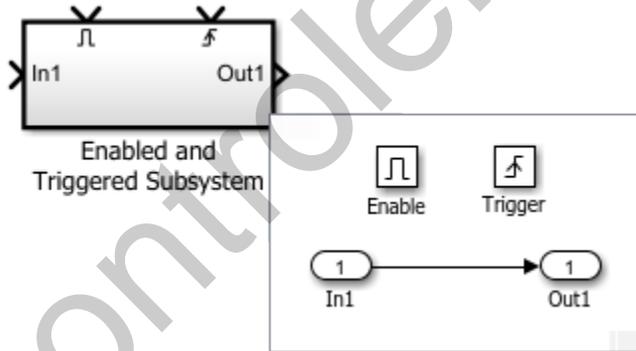

**Library:** Ports & Subsystems

## Description

The Enabled and Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when both of these conditions occur:

- Enable control signal has a positive value.
- Trigger control signal has a trigger event.

Use Enabled and Triggered Subsystem blocks to model:

- Optional functionality that runs with the detection of an event.
- Alternative functionality that runs with the detection of an event.

## Ports

### Input

#### **In** — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### **Enable** — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

#### **Trigger** — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

### Output

#### **Out** — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

## Enabled Subsystem

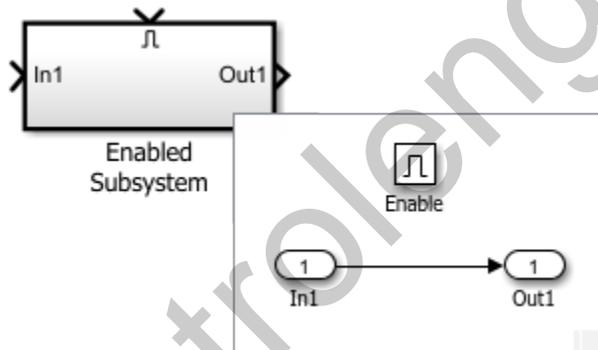

Subsystem whose execution is enabled by external input

**Library:** Ports & Subsystems

### Description

The Enabled Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a positive value.

Use Enable Subsystem blocks to model:

- Discontinuities
- Optional functionality
- Alternative functionality

## Ports

### Input

#### **In** — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### **Enable** — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

### Output

#### **Out** — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

## Enabled Synchronous Subsystem

Represent enabled subsystem that has synchronous reset and enable behavior

### Library

HDL Coder / HDL Subsystems

### Description

An Enabled Synchronous Subsystem is an Enabled Subsystem that uses the Synchronous mode of the State Control block. If an **S** symbol appears in the subsystem, then it is synchronous.

To create an Enabled Synchronous Subsystem block, add the block to your Simulink model from the HDL Subsystems block library. You can also add a State Control block with **State control** set to **Synchronous** inside an Enabled subsystem.

For more information, see **State Control** and “Enabled Subsystems”.

### Data Type Support

See **Input** for information on the data types accepted by a subsystem's input ports. See **Output** for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

#### Settings

**Default:** FromPortIcon

none

Does not display port labels on the subsystem block.

FromPortIcon

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

FromPortBlockName

Display the name of the corresponding port block on the subsystem block.

SignalName

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Read/Write permissions

Control user access to the contents of the subsystem.

### Settings

**Default:** ReadWrite

#### ReadWrite

Enables opening and modification of subsystem contents.

#### ReadOnly

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

#### NoReadOrWrite

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

### Settings

**Default:** ' '

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

### Settings

**Default:** All

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, Simulink.Signal objects).

ExplicitOnly

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

### Settings

**Default:** Off

On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

### Dependencies

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-1779.
- “Sample time (-1 for inherited)” on page 1-1782
- “Function packaging” on page 1-1784 (requires a Simulink Coder license)

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

### Settings

**Default:** On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

### Dependency

“Treat as grouped when propagating variant conditions” on page 1-1778 enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

### Settings

**Default:** Auto

Auto

Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

Inline

Simulink Coder software inlines the subsystem unconditionally.

### Nonreusable function

Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments depending on the “Function interface” on page 1-1793 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-1788 and “File name (no extension)” on page 1-1791. These functions are not reentrant.

### Reusable function

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
HDL Code Generation	Yes

## See Also

### See Also

Introduced in R2016a

controlengineers.ir

# Enumerated Constant

Generate enumerated constant value

## Library

Sources

## Description

The Enumerated Constant block outputs a scalar, array, or matrix of enumerated values. You can also use the **Constant** block to output enumerated values, but it provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**. When you need a block that outputs only constant enumerated values, preferably use Enumerated Constant rather than Constant. For more information, see “Simulink Enumerations”.

## Data Type Support

The Enumerated Constant block supports only enumerated data types. Use the **Constant** block to output constant data of other types. For more information, see “Data Types Supported by Simulink”.

## Parameters

### Output data type

The **Output data type** field specifies the enumerated type from which you want the block to output one or more values. The initial value, Enum: S1DemoSign, is a dummy

enumerated type that prevents a newly cloned block from causing an error. To specify the desired enumerated type, select it from the pulldown or enter **Enum: *ClassName*** in the **Output data type** field, where *ClassName* is the name of the MATLAB class that defines the type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Value

The **Value** field specifies the value(s) that the block outputs. The output of the block has the same dimensions and elements as the **Value** parameter. The initial value, **SlDemoSign.Positive**, is a dummy enumerated value that prevents a newly cloned block from causing an error.

To specify the desired enumerated value(s), select from the pulldown or enter any MATLAB expression that evaluates to the desired result, including an expression that uses tunable parameters. All values specified must be of the type indicated by the **Output data type**. To specify an array that includes every value in the enumerated type, use the **enumeration** function.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Sample time

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

### Settings

**Default:** `inf`

This setting indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output. See “Specify Sample Time” for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Enumerated
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Environment Controller

Create branches of block diagram that apply only to simulation or only to code generation

## Library

Signal Routing

## Description

This block outputs the signal at its Sim port only if the model that contains it is being simulated. It outputs the signal at its Coder port only if code is being generated from the model. This option enables you to create branches of a block diagram that apply only to simulation or code generation. The table below describes various scenarios where either the Sim or Coder port applies.

Scenario	Output
Normal mode simulation	Sim
Accelerator mode simulation	Sim
Rapid Accelerator mode simulation	Sim
Simulation of a referenced model (Normal or Accelerator modes)	Sim
Simulation of a referenced model (Processor-in-the-loop (PIL) mode)	Coder (uses the same code generated for a referenced model)
External mode simulation	Coder
Standard code generation	Coder
Code generation of a referenced model	Coder

Simulink Coder software does not generate code for blocks connected to the Sim port if these conditions hold:

- On the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box, you set **Default parameter behavior** to **Inlined**.
- The blocks connected to the Sim port do not have external signals.
- The Sim port input path does not contain an S-function or an Interpreted MATLAB Function block.

If you enable block reduction optimization, Simulink eliminates blocks in the branch connected to the Coder port when compiling the model for simulation. For information about block reduction, see “Block reduction” in the online Simulink documentation.

---

**Note** Simulink Coder code generation eliminates the blocks connected to the Sim branch only if the Sim branch has the same signal dimensions as the Coder branch. Regardless of whether it eliminates the Sim branch, Simulink Coder uses the sample times on the Sim branch as well as the Coder branch to determine the fundamental sample time of the generated code and might, in some cases, generate sample-time handling code that applies only to sample times specified on the Sim branch.

---

## Data Type Support

The Environment Controller block accepts signals of any data type that Simulink supports. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

**Introduced before R2006a**

## Event Listener

Add event port to subsystem

**Library:** Ports & Subsystems

### Description

Add event port and specify event type for Initialize Function or Terminate Function subsystem blocks.

### Parameters

**Event** — Specify event type for subsystem

Initialize (default) | Terminate | Reset

### Settings

Initialize

Select to trigger the execution of an Initialize Function block with an initialize event.

Terminate

Select to trigger the execution of a Terminate Function block with a terminate event.

Reset

Select to trigger the execution of an Initialize Function block reconfigured as a Reset Function block with a reset event.

**Event name** — Specify event name for Reset Function block

Reset (default) | <character vector>

### Settings

Reset

Default name on the face of the Reset Function block.

<character vector>

User entered name displayed on the face of the Reset Function block, and the name of the reset event port on the Model block containing the Reset Function block.

When typing the name for a reset function, the auto-completion list provides some suggestions. It is not a complete list.

## Dependency

To enable this parameter, set the **Event** parameter to **Reset**.

**Enable variant condition** – Enable variant condition on an Initialize, Reset, or Terminate Function block

Clear (default) | Select

Enabling the variant condition allows the **Variant Control** defined with a Boolean expression to activate the function when condition is **true**.

## Settings

Clear (Off)

Deactivate variant control of subsystem.

Select (On)

Activate variant control of subsystem.

## Dependency

Selecting this parameter, enables **Variant control** and **Generate preprocessor conditionals** parameters.

**Variant control** – Variant control expression that activates function

Variant (default) | <character vector>

## Settings

### Variant

Replace with a boolean expression.

<character vector>

A boolean expression or a `Simulink.Variant` object representing a boolean expression.

The function is activated when the expression evaluates to `true`.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

## Dependency

To enable this parameter, select the **Enable variant condition** parameter.

**Generate preprocessor conditionals** — Determines if variant choices are enclosed within C preprocessor conditional statements

Clear (default) | Select

## Settings

Clear

Does not enclose variant choices within C preprocessor conditional statements.

Select

When generating code for an ERT target, encloses variant choices within C preprocessor conditional statements (`#if`).

## Dependency

To enable this parameter, select the **Enable variant condition** parameter.

## Extract Bits

Output selection of contiguous bits from input signal

## Library

Logic and Bit Operations

## Description

The Extract Bits block allows you to output a contiguous selection of bits from the stored integer value of the input signal. Use the **Bits to extract** parameter to define the method for selecting the output bits.

- Select **Upper half** to output the half of the input bits that contain the most significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation  

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Lower half** to output the half of the input bits that contain the least significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation  

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$
- Select **Range starting with most significant bit** to output a certain number of the most significant bits of the input signal. Specify the number of most significant bits to output in the **Number of bits** parameter.
- Select **Range ending with least significant bit** to output a certain number of the least significant bits of the input signal. Specify the number of least significant bits to output in the **Number of bits** parameter.
- Select **Range of bits** to indicate a series of contiguous bits of the input to output in the **Bit indices** parameter. You indicate the range in [start end] format, and the

indices of the input bits are labeled contiguously starting at 0 for the least significant bit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

## Data Type Support

The Extract Bits block accepts inputs of any numeric data type that Simulink supports, including fixed-point data types. Floating-point inputs are passed through the block unchanged. `Boolean` inputs are treated as `uint8` signals.

---

**Note:** Performing bit operations on a signed integer is difficult. You can avoid difficulty by converting the data type of your input signals to unsigned integer types.

---

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Bits to extract

Select the method for extracting bits from the input signal.

### Number of bits

(Not shown on dialog above.) Select the number of bits to output from the input signal. Signed integer data types can have no less than two bits in them. Unsigned data integer types can be as short as a single bit.

This parameter is only visible if you select `Range starting with most significant bit` or `Range ending with least significant bit` for the **Bits to extract** parameter.

### Bit indices

(Not shown on dialog above.) Specify a contiguous range of bits of the input signal to output. Specify the range in `[start end]` format. The indices are assigned to the input bits starting with 0 at the least significant bit.

This parameter is only visible if you select **Range** of bits for the **Bits to extract** parameter.

### Output scaling mode

Select the scaling mode to use on the output bits selection:

- When you select **Preserve fixed-point scaling**, the fixed-point scaling of the input is used to determine the output scaling during the data type conversion.
- When you select **Treat bit field as an integer**, the fixed-point scaling of the input is ignored, and only the stored integer is used to compute the output data type.

## Example

Consider an input signal that is represented in binary by 110111001:

- If you select **Upper half** for the **Bits to extract** parameter, the output is 11011 in binary.
- If you select **Lower half** for the **Bits to extract** parameter, the output is 11001 in binary.
- If you select **Range starting with most significant bit** for the **Bits to extract** parameter, and specify 3 for the **Number of bits** parameter, the output is 110 in binary.
- If you select **Range ending with least significant bit** for the **Bits to extract** parameter, and specify 8 for the **Number of bits** parameter, the output is 10111001 in binary.
- If you select **Range of bits** for the **Bits to extract** parameter, and specify [ 4 7] for the **Bit indices** parameter, the output is 1011 in binary.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited
Direct Feedthrough	Yes

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Fcn

Apply specified expression to input

## Library

User-Defined Functions

## Description

The Fcn block applies the specified mathematical expression to its input. The expression can include one or more of these components:

- $u$  — The input to the block. If  $u$  is a vector,  $u(i)$  represents the  $i$ th element of the vector;  $u(1)$  or  $u$  alone represents the first element.
- Numeric constants.
- Arithmetic operators (+ - \* / ^).
- Relational operators (== != > < >= <=) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Logical operators (&& || !) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Parentheses.
- Mathematical functions — `abs`, `acos`, `asin`, `atan`, `atan2`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `hypot`, `log`, `log10`, `power`, `rem`, `sgn` (equivalent to `sign` in MATLAB), `sin`, `sinh`, `sqrt`, `tan`, and `tanh`.

---

**Note:** The Fcn block does not support `round` and `fix`. Use the Rounding Function block to apply these rounding modes.

---

- Workspace variables — Variable names that are not recognized in the preceding list of items are passed to MATLAB for evaluation. Matrix or vector elements must be specifically referenced (e.g.,  $A(1, 1)$  instead of  $A$  for the first element in the matrix).

The Fcn block observes the following rules of operator precedence:

- 1 ( )
- 2 ^
- 3 + - (unary)
- 4 !
- 5 \* /
- 6 + -
- 7 > < <= >=
- 8 == !=
- 9 &&
- 10 ||

The expression differs from a MATLAB expression in that the expression cannot perform matrix computations. Also, this block does not support the colon operator (:).

Block input can be a scalar or vector. The output is always a scalar. For vector output, consider using the **Math Function** block. If a block input is a vector and the function operates on input elements individually (for example, the **sin** function), the block operates on only the first vector element.

## Limitations

The Fcn block has the following limitations:

- You cannot tune the expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. To implement tunable expressions, tune the expression outside the Fcn block. For example, use the **Relational Operator** block to evaluate the expression outside.
- The Fcn block does not support custom storage classes. See “Custom Storage Classes” (Embedded Coder) in the Embedded Coder documentation.

## Data Type Support

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Expression

Specify the mathematical expression to apply to the input. Expression components are listed above. The expression must be mathematically well-formed (uses matched parentheses, proper number of function arguments, and so on). The expression has restrictions on tunability (see “Limitations” on page 1-591)

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

The following example models show how to use the Fcn block:

- `sldemo_absbrake`
- `sldemo_enginewc` (Throttle & Manifold/Throttle subsystem)

## Characteristics

Data Types	Double   Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No

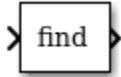

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Find

Find nonzero elements in array

## Library

Math Operations

## Description

The Find block locates all nonzero elements of the input signal and returns the linear indices of those elements. If the input is a multidimensional signal, the Find block can also return the subscripts of the nonzero input elements. In both cases, you can show an output port with the nonzero input values.

## Data Type Support

The Find block accepts and outputs real values of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Index output format” on page 1-595
- “Number of input dimensions” on page 1-596
- “Index mode” on page 1-597
- “Show output port for nonzero input values” on page 1-598
- “Sample time” on page 1-255

- “Output data type” on page 1-600
- “Mode” on page 1-602
- “Data type override” on page 1-198
- “Signedness” on page 1-605
- “Word length” on page 1-606
- “Scaling” on page 1-607

## Index output format

Select the output format for the indices of the nonzero input values.

### Settings

**Default:** Linear indices

#### Linear indices

Provides the element indices of any dimension signal in a vector form. For one dimension (vector) signals, indices correspond to the position of nonzero values within the vector. For signals with more than one dimension, the conversion of subscripts to indices is along the first dimension. You do not need to know the signal dimension of the input signal.

#### Subscripts

Provides the element indices of a two-dimension or larger signal in a subscript form. Because the block shows an output port for each dimension, this option requires you to know the number of dimensions for the input signal.

### Dependencies

Selecting Subscripts from the **Index output format** list enables the **Number of input dimensions** parameter.

### Command-Line Information

**Parameter:** IndexOutputFormat

**Type:** character vector

**Value:** Linear indices | Subscripts

**Default:** Linear indices

## Number of input dimensions

Specify the number of dimensions for the input signal.

### Settings

**Default:** 1

**Minimum:** 1

**Maximum:** 32

### Dependencies

Selecting Subscripts from the **Index output format** list enables this parameter.

### Command-Line Information

**Parameter:** NumberOfInputDimensions

**Type:** int

**Value:** positive integer value

**Default:** 1

controlengineers.ir

## Index mode

Specify the indexing mode.

### Settings

**Default:** Zero-based

#### Zero-based

An index of 0 specifies the first element of the input vector. An index of 1 specifies the second element, and so on.

#### One-based

An index of 1 specifies the first element of the input vector. An index of 2, specifies the second element, and so on.

### Command-Line Information

**Parameter:** IndexMode

**Type:** character vector

**Value:** Zero-based | One-based

**Default:** Zero-based

Controlengineers.ir

## Show output port for nonzero input values

Show or hide the output port for nonzero input values.

### Settings

**Default:** Off

On

Display the output port for nonzero input values. The additional output port provides the values of the nonzero input elements.

Off

Hide the output port for nonzero input values.

### Command-Line Information

**Parameter:** ShowOutputPortForNonzeroInputValues

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'off'

Controlengineers.ir

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Output data type is defined by the target.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16)`

Output data type is fixed point, `fixdt(1,16)`.

`<data type expression>`

Use a data type object, for example, `Simulink.NumericType`.

Click the **Show data type assistant** button  to display additional parameters for the **Output data type** parameter.

### Command-Line Information

**Parameter:** `OutDataTypeStr`

**Type:** character vector

**Value:** 'Inherit: Inherit via internal rule' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | '<data type expression>'

**Default:** 'Inherit: Inherit via internal rule'

**See Also**

“Control Signal Data Types”, “Specify Data Types Using Data Type Assistant”

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second list of the possible values:

- **Inherit via internal rule** (Discrete-Time Integrator, Gain, Product, Sum, Switch block default)

#### Built in

Built-in data types. Selecting **Built in** enables a second list of the possible values:

- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second text box, where you can enter the expression.

### Dependencies

Clicking the **Show data type assistant** button enables this parameter.

Selecting **Fixed point** from the **Mode** list enables the following parameters:

- **Signed**
- **Scaling**

- Word length

### See Also

“Specify Data Types Using Data Type Assistant”

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether the fixed-point data is signed or unsigned.

### Settings

**Default:** Signed

Signed

Specifies the fixed-point data as signed.

Unsigned

Specifies the fixed-point data as unsigned.

### Dependency

Selecting **Fixed point** from the **Mode** list enables this parameter.

Controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependency

Selecting **Fixed point** from the **Mode** list enables this parameter.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Integer

#### Integer

Specifies a binary point location for fixed-point data and sets the fraction length to 0.

The **Scaling** list has only one item for you to select.

### Dependency

Selecting **Fixed point** from the **Mode** list enables this parameter.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced in R2010a**

## First-Order Hold

Implement first-order sample-and-hold

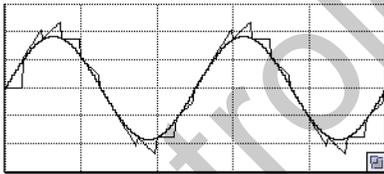

### Library

Discrete

### Description

The First-Order Hold block implements a first-order sample-and-hold that operates at the specified sampling interval. This block has little value in practical applications and is included primarily for academic purposes.

This figure compares the output from a Sine Wave block and a First-Order Hold block.

### Data Type Support

The First-Order Hold block accepts and outputs signals of type **double**. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

Sample time

The time interval between samples. See “Specify Sample Time” in the online documentation for more information.

## Characteristics

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Zero-Order Hold

Introduced before R2006a

## Fixed-Point State-Space

Implement discrete-time state space

$$\begin{cases} y(n) = Cx(n) + Du(n) \\ x(n+1) = Ax(n) + Bu(n) \end{cases}$$

### Library

Additional Math & Discrete / Additional Discrete

### Description

The Fixed-Point State-Space block implements the system described by

$$y(n) = Cx(n) + Du(n)$$

$$x(n + 1) = Ax(n) + Bu(n)$$

where  $u$  is the input,  $x$  is the state, and  $y$  is the output. Both equations have the same data type.

The matrices A, B, C and D have the following characteristics:

- A must be an n-by-n matrix, where n is the number of states.
- B must be an n-by-m matrix, where m is the number of inputs.
- C must be an r-by-n matrix, where r is the number of outputs.
- D must be an r-by-m matrix.

In addition:

- The state  $x$  must be an n-by-1 vector.
- The input  $u$  must be an m-by-1 vector.

- The output  $y$  must be an  $r$ -by-1 vector.

The block accepts one input and generates one output. The block determines the input vector width by the number of columns in the  $B$  and  $D$  matrices. Similarly, the block determines the output vector width by the number of rows in the  $C$  and  $D$  matrices.

## Data Type Support

The Fixed-Point State-Space block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### State Matrix $A$

Specify the matrix of states.

### Input Matrix $B$

Specify the column vector of inputs.

### Output Matrix $C$

Specify the column vector of outputs.

### Direct Feedthrough Matrix $D$

Specify the matrix for direct feedthrough.

### Initial condition for state

Specify the initial condition for the state.

### Data type for internal calculations

Specify the data type for internal calculations.

### Scaling for State Equation $AX+BU$

Specify the scaling for state equations.

### Scaling for Output Equation CX+DU

Specify the scaling for output equations.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# Floating Scope and Scope Viewer

Display signals generated during simulation

## Library

Sinks

## Description

The Simulink Floating Scope block and Scope Viewer display time domain signals with respect to simulation time.

Input signal characteristics:

- **Signal** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Signal data type** — Any data type that Simulink supports including real, complex, fixed-point, and enumerated data types. See “Data Types Supported by Simulink”.
- **Signal dimension** — Scalar, one-dimensional (vector), two dimensional (matrix), or multidimensional. Display multiple channels within a signal depending on its dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Floating Scope block characteristics:

- **Multiple y-axes (displays)** — Display multiple  $y$ -axes with multiple input ports. All of the  $y$ -axes have a common time range on the  $x$ -axis.
- **Multiple signals** — Show multiple signals on the same  $y$ -axis (display) from one or more input ports.
- **Modify parameters** — Modify scope parameter values before and during a simulation.
- **Display data after simulation** — If a Floating Scope is closed at the start of a simulation, scope data is still written to the scope during a simulation. As a result, if

you open the Floating Scope after a simulation, the scope displays simulation results for input signals.

---

**Note:** A Floating Scope block and Scope Viewer have the same functionality as a Scope block, but they are not connected to signal lines. Use the Signal Selector to add and display signals on a Floating Scope.

---

---

**Note:** If you step back the simulation after adding or removing a signal, the Floating Scope clears the existing data. New data does not appear until the simulation steps forward again.

---

---

**Note:** Scope Viewer may plot a single point when connected to a constant signal.

---

---

**Note:** Simulink messages are not supported for Floating Scope block and Scope Viewer.

---

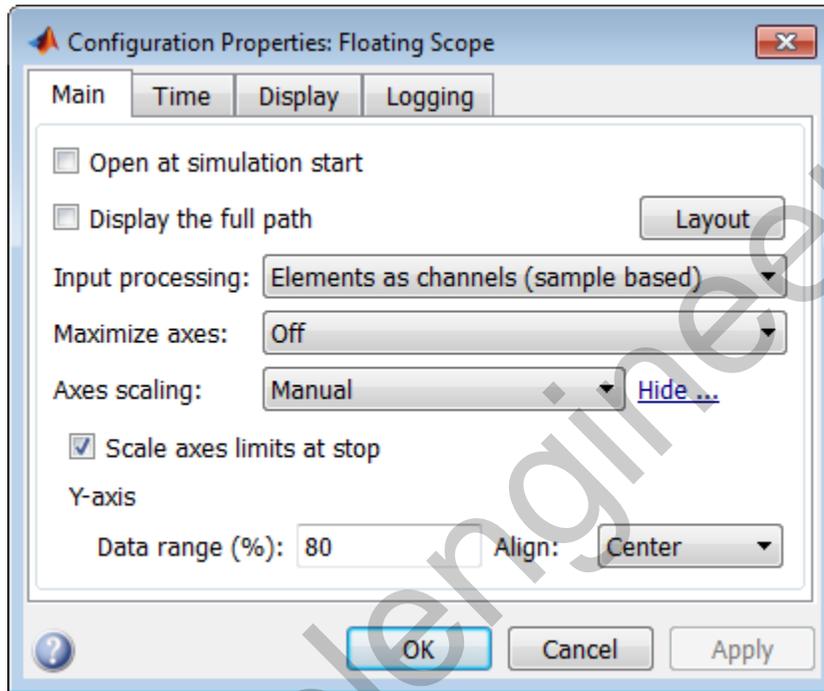

---

**Note:** For information on controlling a Floating Scope programmatically, see “Control Scopes Programmatically” in the Simulink documentation.

---

When you use model configuration parameters such as **Signal storage reuse** and **Block reduction** for a faster simulation and optimized generated code, Simulink eliminates storage for some signals during simulation. You are unable to apply a Floating Scope to these eliminated signals. To work around this issue, configure an eliminated signal as a test point. You can then apply a Floating Scope to the signal regardless of optimization settings. To configure test points, see “Test Points”.

## Configuration Properties

### Open at simulation start

Specify when a Scope window opens.

#### Settings

**Default:** Clear for Scope block. Select for Time Scope block.

Select

Open Scope window when simulation starts.

Clear

Do not open a closed Scope at the start of a simulation.

## Display the full path

Display full block path on Scope title bar.

### Settings

**Default:** Clear

- Select  
Display block path and name.
- Clear  
Display block name.

Scope Configuration property: No corresponding property.

## Number of input ports

Specify number of input ports on a Scope block, specified by a positive integer character vector. Maximum number of input ports is 96. This property does not apply to floating scopes and scope viewers.

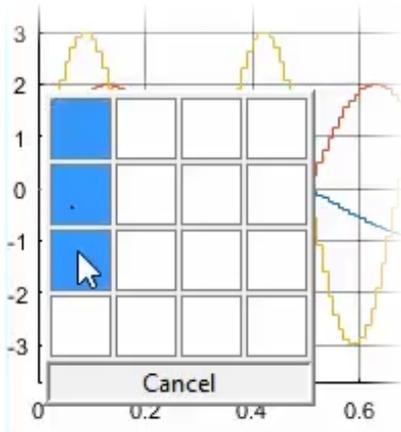

**Default:** 1

Scope Configuration property: NumInputPorts.

## Layout button

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

- If the number of displays are equal to the number of ports, signals from each port appear on separate displays.
- If the number of displays are less than the number of ports, signals from additional ports appear on the last display.
- For layouts with multiple columns and rows, ports are mapped down then across.

### Settings

**Default:** 1 display

Scope Configuration property: `LayoutDimensions`.

### Sample time

Specify time interval between Scope block updates during a simulation, specified as a positive real character vector. This property does not apply to floating scopes and scope viewers.

### Settings

**Default:** -1 for inherited

Scope Configuration property: `SampleTime`.

### Input processing

Specify sample-based or frame-based processing of signals.

### Settings

**Default:** Elements as channels (sample based) for Scope block. Columns as channels (frame based) for Time Scope block.

Elements as channels (sample based)

Process signal values in a channel at each time interval.

Columns as channels (frame based)

Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Scope Configuration property: FrameBasedProcessing.

### Maximize axes

Maximize size of signal plots. Each of the plots expands to fit the full display. Maximizing the size of signal plots removes the background area around the plots.

### Settings

**Default:** Off for Scope block. Auto for Time Scope block.

Auto

If **Title** and **Y-label** properties are not specified, maximize all plots.

On

Maximize all plots. Values in **Title** and **Y-label** are hidden

Off

Do not maximize plots.

Scope Configuration property: MaximizeAxes.

### Axes scaling

Specify when to scale y-axis to include all signal values.

### Settings

**Default:** Manual

Manual

Manually scale y-axis range with **Scale Y-axis Limits** toolbar button.

#### Auto

Scale y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box.

If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to **Auto** and clear the **Do not allow Y-axis limits to shrink** check box.

#### After N Updates

Scale y-axis after the number of time steps specified in the Number of updates text box. Scaling occurs once during each run.

### Do not allow Y-axis limits to shrink

Specify when y-axis range limits can change.

#### Settings

**Default:** Select

Select

Allow y-axis range limits to increase but not decrease during a simulation.

Clear

Allow y-axis range limits to increase and decrease.

#### Dependency

Click the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to **Auto** to display this property.

### Number of updates

Specify the number of updates that occur during a simulation before a Scope scales the y-axes, specified as a positive integer character vector.

#### Settings

**Default:** 10

## Dependency

Display and activate this property by clicking the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to After N Updates.

Scope Configuration property: AxesScalingNumUpdates.

## Scale axes limits at stop

Specify when to scale axes.

### Settings

**Default:** Select

- Select  
Scale axes when simulation stops.
- Clear  
Always scale axes.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

The *y*-axis limits are always scaled. The *x*-axis limits are scaled only if you also select the **Autoscale X-axis limits** check box.

## Y-axis Data range (%)

Specify percentage of *y*-axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire *y*-axis range.

### Settings

**Default:** 80

Values are 1 through 100.

## Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

## Y-axis Align

Specify where to align plotted data along the  $y$ -axis data range when **Y-axis Data range** is set to less than 100 percent.

### Settings

**Default:** Center

Top

Align signals with maximum values at top of  $y$ -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of  $y$ -axis range.

## Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

## Autoscale X-axis limits

Scale  $x$ -axis range limits when scaling axes.

### Settings

**Default:** Clear

Select

Scale  $x$ -axis range to fit all signal values. If **Axes scaling** is set to **Auto**, scales the data currently within the axes, not the entire signal in the data buffer.

Clear

Do not scale  $x$ -axis range.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### X-axis Data range (%)

Specify percentage of  $x$ -axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire  $x$ -axis range.

### Settings

**Default:** 100

Values are 1 through 100.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### X-axis Align

Specify where to align plotted data along the  $x$ -axis when **X-axis Data range** is set to less than 100 percent.

### Settings

**Default:** Center

Top

Align signals with maximum values at top of  $x$ -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of  $x$ -axis range.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### Time span

Specify length of  $x$ -axis range to display.

The block calculates the beginning and end times of the time range using the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

### Settings

**Default:** Auto

Auto

Difference between the simulation start and stop times.

User defined

Value less than the total simulation time.

Scope Configuration property: TimeSpan.

### Time span overrun action

Specify how to display data beyond the visible  $x$ -axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

### Settings

**Default:** Wrap

Wrap

Draw a full screen of data from left to right, clear the screen, and then restart drawing of data.

## Scroll

Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Scope Configuration property: `TimeSpanOverrunAction`.

## Time units

Display units for the  $x$ -axis.

### Settings

**Default:** `None` for Scope block. `Metric` for Time Scope block.

### Metric

Display time units based on the length of **Time span**.

### Seconds

Display Time (seconds).

### None

Do not display time units.

Scope Configuration property: `TimeUnits`.

## Time display offset

Offset the  $x$ -axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scaler or vector.

- Scaler — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

### Settings

**Default:** `0`

Scope Configuration property: `TimeDisplayOffset`.

## Time-axis labels

Specify how  $x$ -axis (time) labels display

### Settings

**Default:** Bottom Displays Only for Scope block. All for Time Scope block.

All

Display  $x$ -axis labels on all  $y$ -axes.

None

Do not display labels. Selecting **None** also clears the **Show time-axis label** check box.

Bottom Displays Only

Display  $x$ -axis label on the bottom  $y$ -axis.

### Dependency

Set **Active display** before setting this property. Activate this property by selecting **Show time-axis label** and setting **Maximize axes** to off.

Scope Configuration property: TimeAxisLabels.

## Show time-axis label

Display or hide  $x$ -axis (time) labels.

### Settings

**Default:** Clear for Scope block. Select for Time Scope block.

Select

Display  $x$ -axis label for the active display

Clear

Hide  $x$ -axis labels.

### Dependency

Set **Active display** before setting this property. If you select this property and set the **Time-axis labels** is set to **NONE**, this property is deactivated.

Scope Configuration property: `ShowTimeAxisLabel`.

## Active display

Display for setting display-specific properties, specified as a positive integer. The number of a display corresponds to its column-wise placement index.

### Settings

**Default:** 1

### Dependency

Setting this property selects the display for setting the properties **Show Grid**, **Show legend**, **Title**, **Plot signals as magnitude and phase**, **Y-label**, and **Y-Limits**.

Scope Configuration property: `ActiveDisplay`.

## Title

Specify a title for display, specified as a character vector. The default value `%<SignalLabel>` uses the input signal name for the title.

### Settings

**Default:** `%<SignalLabel>`

### Dependency

Set **Active display** before setting this property.

Scope Configuration property: `Title`.

## Show legend

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. See the **SCOPE** block reference for an example.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

## Settings

**Default:** Clear

Select

Display signal legend. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

Clear

Hide signal legend.

## Dependency

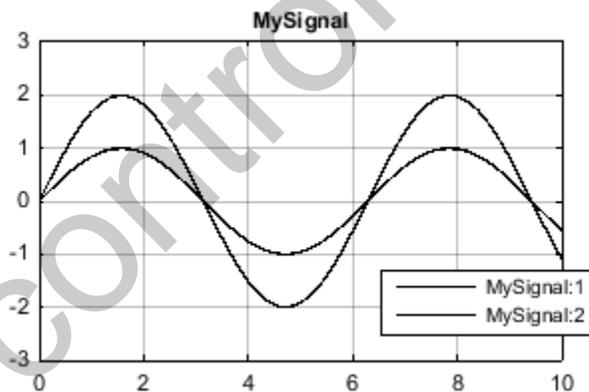

Set **Active Display** before setting this property.

Scope Configuration property: ShowLegend.

## Example

Connect a Sine Wave block to a Scope. Set the **Amplitude** parameter for the Sine Wave to [ 1 2]. Select the **Legends** check box for the Scope. Set the **Signal name** property for the signal to MySignal.

After simulating this model, the Scope window displays a sine wave for the two signal channels in MySignal, MySignal:1, and MySignal:2.

Edit the name of any channel in the legend by double-clicking the current name and entering a new channel name.

See also “Signal Dimensions” and “Determine Output Signal Dimensions”.

## Show grid

Show vertical and horizontal grid lines.

### Settings

**Default:** Select

- Select  
Display grid lines.
- Clear  
Hide grid lines.

### Dependency

Set **Active Display** before setting this property.

Scope Configuration property: ShowGrid.

## Plot signals as magnitude and phase

Split display into magnitude and phase plots.

### Settings

**Default:** Clear

- Select  
Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values.
- Clear  
Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

### Dependency

Set **Active Display** before setting this property.

Scope Configuration property: PlotAsMagnitudePhase.

### Y-limits (Minimum)

Specify minimum value of y-axis.

### Settings

Default: -10

### Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The y-axis limits of the phase plot are always [ -180 180].

Scope Configuration property: YLimits.

### Y-limits (Maximum)

Specify maximum value of y-axis, specified as real number.

### Settings

Default: +10

### Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The y-axis limits of the phase plot are always [ -180 180].

Scope Configuration property: YLimits.

### Y-label

Specify y-axis label, specified as a character vector.

## Settings

**Default:** No label for Scope block. **Amplitude** for Time Scope block.

## Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** hides this property and plots are labeled **Magnitude** and **Phase**.

Scope Configuration property: YLabel1.

## Limit data points to last

Specify to limit buffered data values before plotting and saving signals.

## Settings

**Default:** Clear, 5000

### Select

Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

In some cases, for example where the sample time is small, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation. If a scope plots a portion of your signals, consider increasing the number of data values to save.

### Clear

Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

## Dependency

If this property is selected, also specify the number of data points by entering a positive integer in the text box. This property limits the data values a scope plots and the data

values saved in the MATLAB variable specified in **Variable name**. Data values are from the end of a simulation.

Scope Configuration properties: DataLoggingLimitDataPoints and DataLoggingMaxPoints.

## Decimation

Reduce the amount of scope data to display and save.

### Settings

**Default:** Clear, 2

Select

Plot and Log (save) scope data every Nth data point, where N is the decimation factor entered in the text box.

Clear

Save all scope data values.

### Dependency

If this property is selected, also specify the decimation factor by entering a positive integer in the text box. The scope buffers every Nth data point, where N is the decimation factor you specify. A value of 1 buffers all data values. This property limits the data values a scope plots and the data values saved in the MATLAB variable specified in **Variable name**.

## Log/Unlog Viewed Signals to Workspace

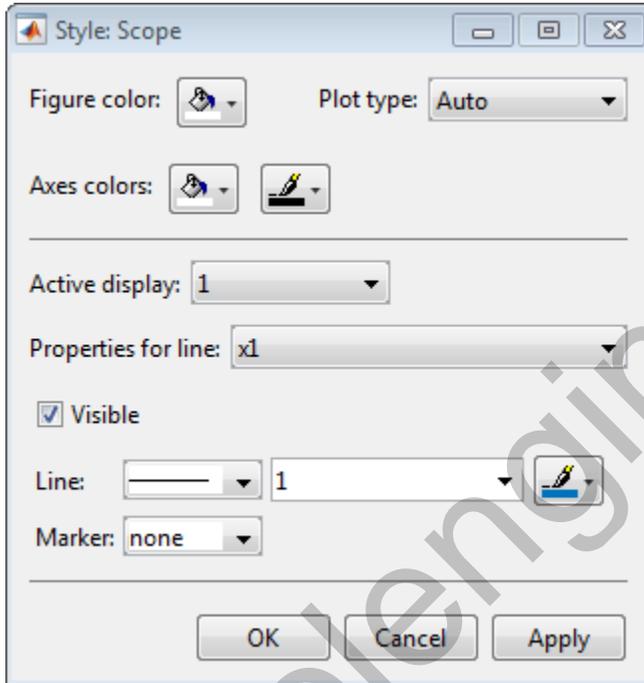

For signals selected with the Signal Selector, clicking this button selects the **Log signal data** check boxes in the Signals Properties dialog boxes.

Clicking the button a second time clears the **Log signal data** check boxes.

## Style Properties

Open the Style dialog box:

- From the menu, select **View > Style**.
- From the Configuration Properties button arrow, select the Style button .

### Figure color

Select background color for display.

### Plot type

Specify how to plot a signal.

**Default:** Auto for Scope block. Line for Time Scope block.

- **Line** — Line graph.
- **Stairs** — Stair-step graph.
- **Auto** — Line graph if it is a continuous signal or a stair-step graph if it is a discrete signal.

### Active display

Select active display for setting style properties.

**Default:** 1

### Axes colors

Select the background color for axes (displays) with the first color pallet. Select the grid and label color with the second color pallet.

### Properties for line

Select active line for setting line style properties.

### Visible

Plot signal on active display.

**Default:** Select

- Select  
Plot signal.
- Clear  
Hide signal.

### Line

Select line style, width, and color.

### Marker

Select marker style.

**Default:** None

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated

## For Each

Enable blocks inside For Each Subsystem to process elements or subarrays of a mask parameter or input signal independently

## Library

Ports & Subsystems

## Description

The For Each block serves as a control block for the For Each Subsystem block. Specifically, the For Each block enables the blocks inside the For Each Subsystem to process elements of the mask parameters or input signals independently. Each block inside this subsystem that has states maintains a separate set of states for each element or subarray it processes. As the set of blocks in the subsystem process the elements (or subarrays), the subsystem concatenates the results to form output signals.

## Iterations in the For Each Subsystem

You can use a For Each subsystems to iteratively compute output after changing inputs or mask parameters. This is done by configuring the partitioning them in the For Each block dialog box.

## Partition Input Signals to the Subsystem

In a For Each subsystem, you can specify which input signals to partition for each iteration, using the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, you also have to specify the **Partition Dimension** and **Partition Width** parameters. For more information, see “Select Partition Parameters” on page 1-636.

## Partition Parameters in the For Each block

You can partition the mask parameters of For Each subsystems. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystems, see “Create a Simple Mask”. To select the mask parameter for partitioning, use the Parameter Partition tab on the For Each block dialog box. For more information, see “Select Partition Parameters” on page 1-636

## Concatenate Output

You define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the Output Concatenation tab.

The results generated by the block for each subarray stack along the concatenation dimension,  $d_1$  (y-axis). Whereas, if you specify  $d_2$  by setting the concatenation dimension to 2, the results concatenate along the  $d_2$  direction (x-axis). Thus if the process generates row vectors, then the concatenated result is a row vector.

## Select Partition Parameters

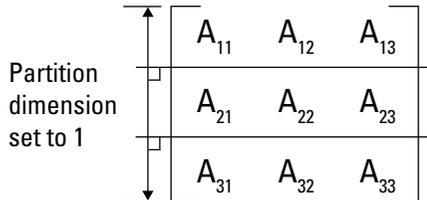

When selecting an input signal or subsystem mask parameter for partitioning, you need specify how to decompose it into elements or subarrays for each iteration. Do this by setting integer values for the **Partition Dimension** and the **Partition Width** parameters.

As an illustration, consider a mask parameter A of the form:

The labels  $d_1$  and  $d_2$ , respectively define dimension 1 and dimension 2. If you retain the default setting of 1 for both the partition dimension and the partition width, then

Simulink slices perpendicular to partition dimension  $d_1$  at a width equal to the partition width, one element.

Mask parameter A decomposes into the following three row vectors:

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \end{bmatrix}$$

$$\begin{bmatrix} A_{21} & A_{22} & A_{23} \end{bmatrix}$$

$$\begin{bmatrix} A_{31} & A_{32} & A_{33} \end{bmatrix}$$

If instead you specify  $d_2$  as the partition dimension by entering the value 2, Simulink slices perpendicular to  $d_2$  to form three column vectors:

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix}$$

$$\begin{bmatrix} A_{12} \\ A_{22} \\ A_{32} \end{bmatrix}$$

$$\begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \end{bmatrix}$$

---

**Note:** Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors according to their orientation. To partition a row vector, specify the partition dimension as 2 (along the columns). To partition a column vector, specify the partition dimension as 1 (along the rows).

---

## Parameters

- “Input Partition Tab” on page 1-638

- “Output Concatenation Tab” on page 1-638
- “Parameter Partition Tab” on page 1-639

## Input Partition Tab

Use this tab to select each input signal you need to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. See the **Inport** block reference page for more information.

### Port

The **Port** column displays the input index and the name of the input port connected to the For Each Subsystem block.

### Partition

Select the check box beside each input signal that you want to partition into subarrays or elements. Selecting this check box enables **Partition Dimension** and **Partition Width** for that input signal.

**Default:** Off

### Partition Dimension

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

**Default:** 1

**Minimum:** 1

### Partition Width

Specify the width of each partition slice of the input signal. The default width of 1 represents a width of one element.

**Default:** 1

**Minimum:** 1

## Output Concatenation Tab

For each output port, specify the dimension along which to stack (concatenate) the For Each Subsystem results. See the **Outport** block reference page for more information.

## Port

The **Port** column displays the output index and the name of the output port connected to the For Each Subsystem block. You can have any number of ports.

## Concatenation Dimension

Specify the dimension along which to stack the results of the For Each Subsystem.

**Default:** 1

**Minimum:** 1

If you specify the default, the results stack in the  $d_1$  direction. Thus if the block generates column vectors, the concatenation process results in a single column vector. If you specify 2, the results stack in the  $d_2$  direction. Thus if the block generates row vectors, the concatenation process results in a single row vector.

## Parameter Partition Tab

Use this tab to select each mask parameter to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. Parameters appear in the list only if you have added an editable parameter to the mask of the parent For Each subsystem.

### Parameter

The **Parameter** column displays the name of the mask parameter of the For Each Subsystem block.

### Partition

Select the check box next to each mask parameter that you want to partition into subarrays or elements. Selecting this check box makes the **Partition Dimension** and **Partition Width** parameters available for that mask parameter.

**Default:** Off

### Partition Dimension

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

**Default:** 1

**Minimum:** 1

### Partition Width

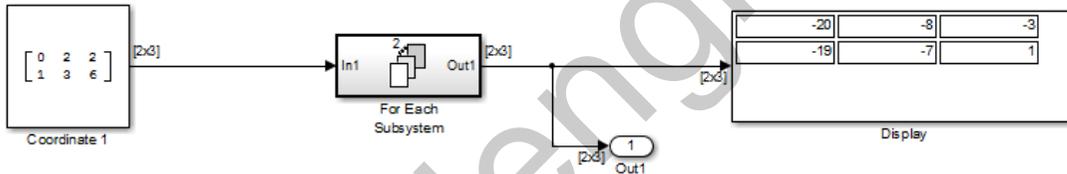

Specify the width of each partition slice of the input signal. The default width of 1 represents a width of one element.

**Default:** 1

**Minimum:** 1

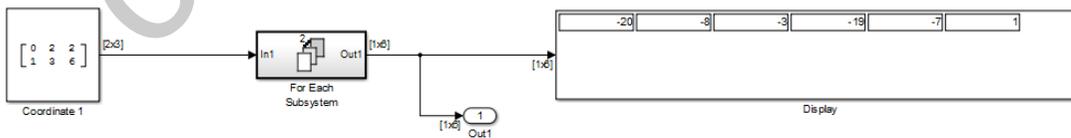

### Examples

The following model demonstrates the partitioning of an input signal by a For Each block. Each row of this 2-by-3 input array contains three integers that represent the ( $x$ ,  $y$ ,  $z$ )-coordinates of a point. The goal is to translate each of these points based on a new origin at  $(-20, -10, -5)$  and to display the results.

By placing the process of summing an input signal and the new origin inside of a For Each Subsystem, you can operate on each set of coordinates by partitioning the input signal into two row vectors. To accomplish such partitioning, use the default settings of 1 for both the partition dimension and the partition width. If you also use the default concatenation dimension of 1, each new set of coordinates stacks in the  $d_1$  direction, making your display a 2-by-3 array.

Alternatively, if you specify a concatenation dimension of 2, then you get a single row vector because each set of results stacks in the  $d_2$  direction.

This example shows how to partition an input signal. To learn how the For Each block and subsystem handle a model with states, see the For Each Subsystem documentation.

## For Each Subsystem

Repeatedly perform algorithm on each element or subarray of input signal and concatenate results

### Library

Ports & Subsystems

### Description

The For Each Subsystem block is useful in modeling scenarios where you need to repeat the same algorithm for individual elements (or subarrays) of an input signal. The set of blocks within the subsystem represents the algorithm applied to a single element (or subarray) of the original signal. The **For Each** block inside the subsystem allows you to configure the decomposition of the subsystem inputs into elements (or subarrays), and to configure the concatenation of the individual results into output signals.

Inside this subsystem, each block that has states maintains separate sets of states for each element or subarray that it processes. Consequently, the operation of this subsystem is similar in behavior to copying the contents of the subsystem for each element in the original input signal and then processing each element using its respective copy of the subsystem.

An additional benefit of the For Each Subsystem is that, for certain models, it improves the code reuse in Simulink Coder generated code. Consider a model containing two reusable Atomic Subsystems with the same scalar algorithm applied to each element of the signal. If the input signal dimensions of these subsystems are different, Simulink Coder generated code includes two distinct functions. You can replace these two subsystems with two identical For Each Subsystems that are configured to process each element of their respective inputs using the same algorithm. For this case, Simulink Coder generated code consists of a single function parameterized by the number of input

signal elements. This function is invoked twice — once for each unique instance of the For Each Subsystem in the model. For each of these cases, the input signal elements have different values.

## Limitations

The For Each Subsystem block has these limitations, which you can work around.

Limitation	Workaround
You cannot log bus or array of bus signals directly in the For Each subsystem.	Use one of these approaches: <ul style="list-style-type: none"> <li>• Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging.</li> <li>• Attach the signal to an Outport block and log the signal outside of the For Each subsystem.</li> </ul>
You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists: <ul style="list-style-type: none"> <li>• The For Each subsystem is in a model simulating in rapid accelerator mode.</li> <li>• The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.</li> </ul>	For the first condition, use accelerator mode. For the second condition, use normal or rapid accelerator mode.
You cannot log the states of the blocks in a For Each subsystem .	Save and restore the simulation state (SimState).
You cannot use normal mode to simulate a Model block inside a For Each subsystem.	Use acclerator or rapid accelerator mode.
Reusable code is generated for two For Each Subsystems with identical contents if their input and output signals are vectors ( 1-D or 2-D row or column vector). For n-D input and output signals, reusable code is generated only when the dimension along which the signal is partitioned is the highest dimension.	Permute the signal dimensions to transform the partition dimension and the concatenation dimension to the highest nonsingleton dimension for n-D signals.

The For Each Subsystem block does not support the following features:

- You cannot include the following blocks or S-functions inside a For Each Subsystem:
  - Data Store Memory, Data Store Read, or Data Store Write blocks inside the subsystem
  - The From Workspace block if the input is a **Structure with Time** that has an empty time field.
  - The To Workspace and To File data saving blocks
  - Goto and From blocks that cross the subsystem boundary.
  - Model Reference block with simulation mode set to 'Normal'
  - Shadow Inports
  - ERT S-functions

For a complete list of the blocks that support the For Each Subsystem, type `showblockdatatypetable` at the MATLAB command line.

- You cannot use the following kinds of signals:
  - Test-pointed signals or signals with an external storage class inside the system
  - Frame signals on subsystem input and output boundaries
  - Variable-size signals
  - Function-call signals crossing the boundaries of the subsystem
- Creation of a linearization point inside the subsystem
- Propagating the Jacobian flag for the blocks inside the subsystem. You can check this condition in MATLAB using `J.Mi.BlockAnalyticFlags.jacobian`, where `J` is the Jacobian object. To verify the correctness of the Jacobian of the For Each Subsystem, perform the following steps
  - Look at the tag of the For Each Subsystem Jacobian. If it is “not\_supported”, then the Jacobian is incorrect.
  - Move each block out of the For Each Subsystem and calculate its Jacobian. If any block is “not\_supported” or has a warning tag, the For Each Subsystem Jacobian is incorrect.
- You cannot perform the following kinds of code generation:
  - Generation of a Simulink Coder S-function target

- Simulink Coder code generation under both of the following conditions:
  - A Stateflow or MATLAB Function block resides in the subsystem.
  - This block tries to access global data outside the subsystem, such as Data Store Memory blocks or Simulink.Signal objects of ExportedGlobal storage class.
- PLC code generation

## S-Function Support

The For Each Subsystem block supports both C-MEX S-functions and Level-2 MATLAB S-functions, provided that the S-function supports multiple execution instances using one of the following techniques:

- A C-MEX S-function must declare `ssSupportsMultipleExecInstances(S, true)` in the `mdlSetWorkWidths` method.
- A Level-2 MATLAB S-function must declare `'block.SupportsMultipleExecInstances = true'` in the `Setup` method.

If you use the above specifications:

- Do not cache run-time data, such as `DWork` and Block I/O, using global or persistent variables or within the `userdata` of the S-function.
- Every S-function execution method from `mdlStart` up to `mdlTerminate` is called once for each element processed by the S-function, when it is in a For Each Subsystem. Consequently, you need to be careful not to free the same memory on repeated calls to `mdlTerminate`. For example, consider a C-MEX S-function that allocates memory for a run-time parameter within `mdlSetWorkWidths`. The memory only needs to be freed once in `mdlTerminate`. As a solution, set the pointer to be empty after the first call to `mdlTerminate`.

## Data Type Support

The For Each Subsystem block accepts real or complex signals of the following data types:

- Floating point

- Built-in integer
- Fixed point
- Boolean
- Non-virtual bus
- Enumerated

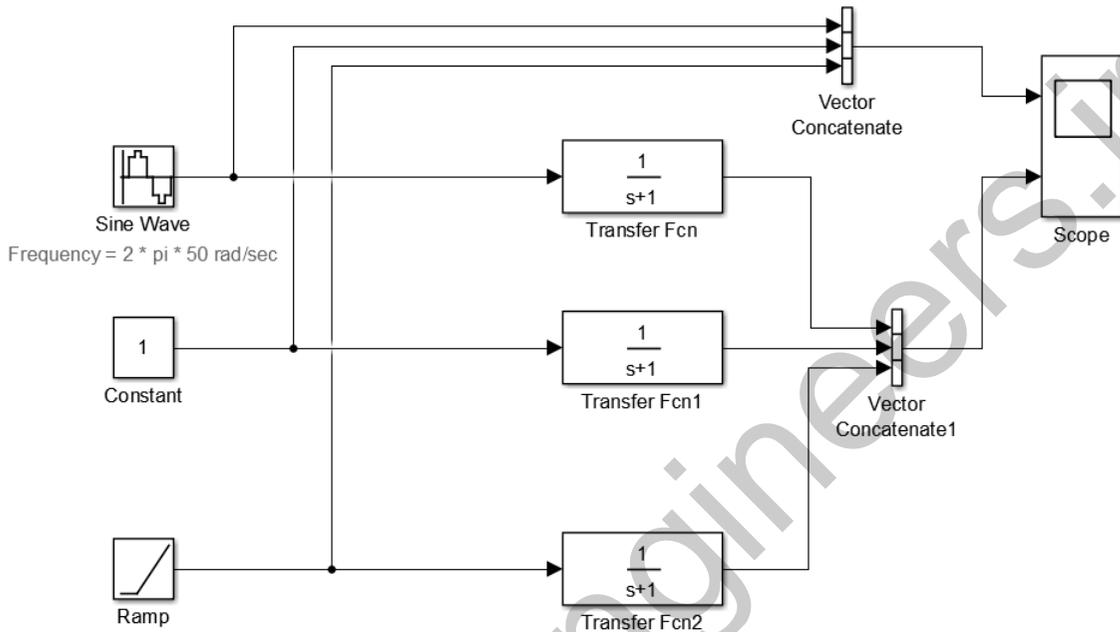

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples of Working with For Each Subsystems

### Vectorize Algorithms Using For Each Subsystems

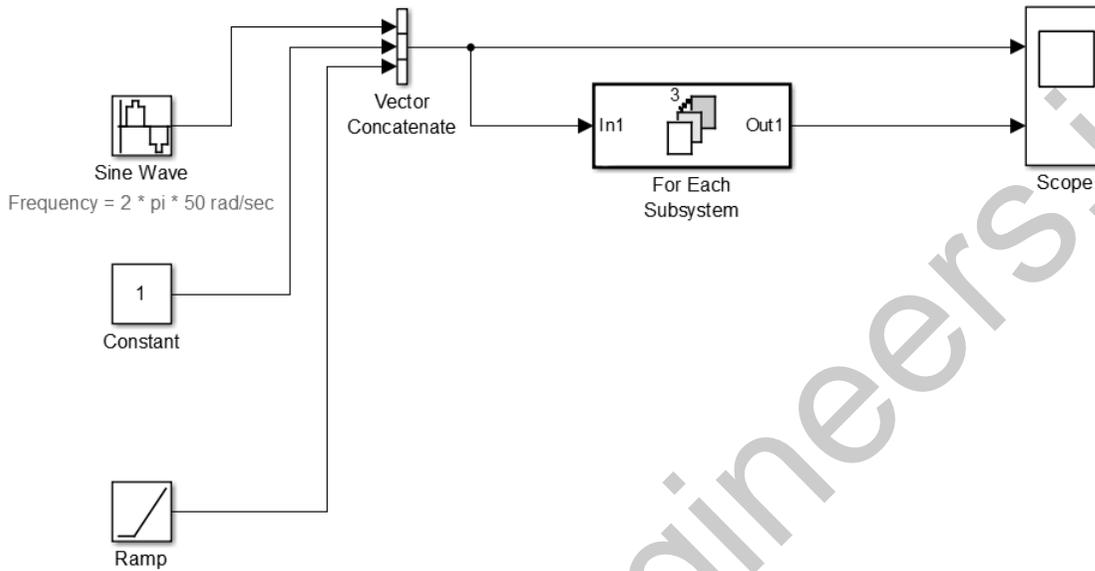

This example shows how to simplify modeling of vectorized algorithms. Using For Each subsystem blocks simplifies a model where three input signals are filtered by three identical Transfer Fcn blocks. This example also shows how to add more control to the filters by changing their coefficients for each iteration of the subsystem.

This model uses identical Transfer Fcn blocks to independently process each element of the input sine wave signal. A Vector Concatenate block concatenates the resulting output signals. This repetitive process is graphically complex and difficult to maintain. Also, adding another element to the signal requires significant reworking of the model.

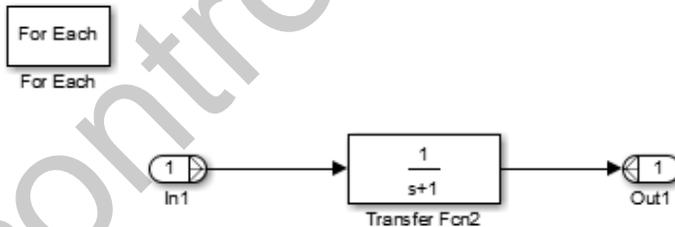

You can simplify this model by replacing the repetitive operations with a single For Each Subsystem block.

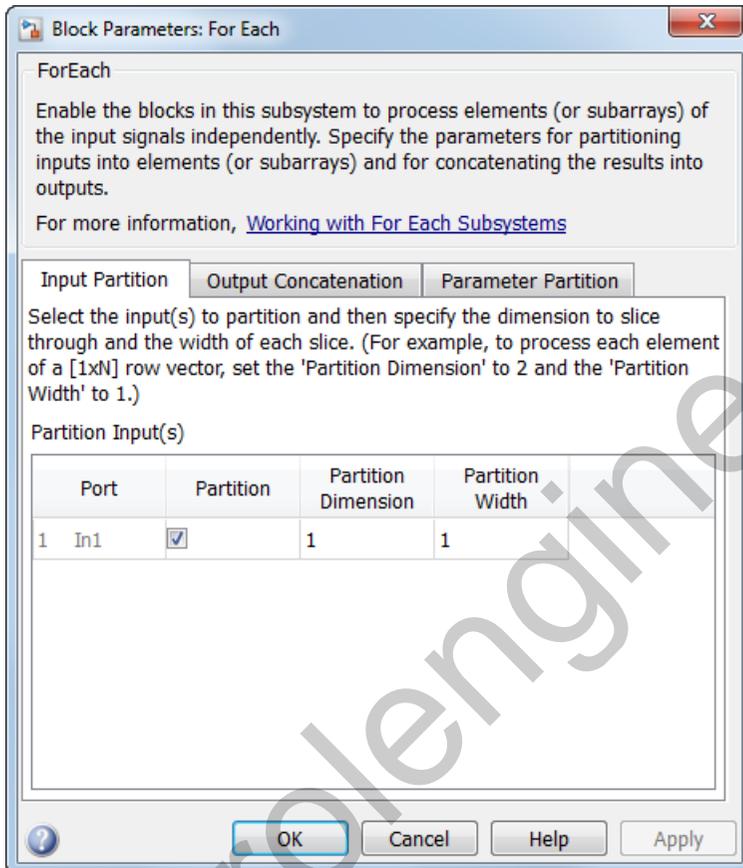

# 1 Blocks – Alphabetical List

The For Each subsystem contains a For Each block and a model representing the algorithm of the three blocks it replaces by way of the Transfer Fcn block. The For Each block specifies how to partition the input signal vector into individual elements and how to concatenate the processed signals to form the output signal vector. Every block that has a state maintains a separate set of states for each input element processed during a given execution step.

For this example, the input signal is selected for partitioning. The **Partition Dimension** and the **Partition Width** parameters on the For Each block are both set to 1 for the input.

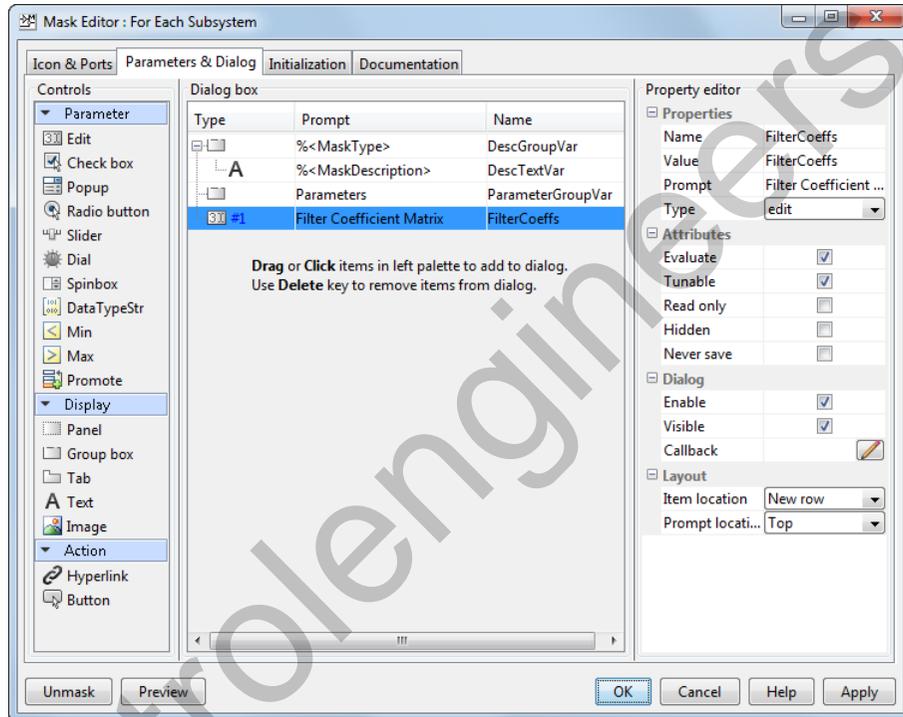

You can scale up this approach to add more signals without having to change the model significantly. This approach is considered easily scalable and graphically simpler.

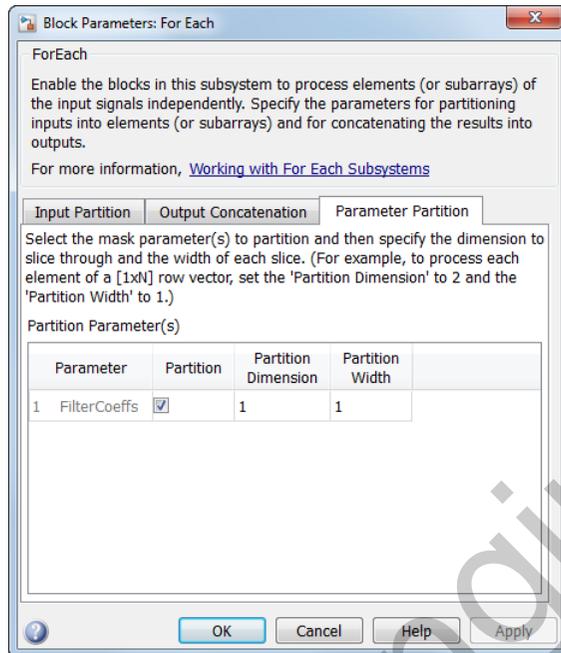

## Model Parameter Variation Without Changing Model Structure

This example shows how to model parameter variation in an algorithm. It uses the For Each Subsystem partitioning model from “Vectorize Algorithms Using For Each Subsystems” on page 1-646 and creates different filters for each input signal while retaining model simplicity. You do this by feeding an array of filter coefficients to the For Each subsystem as a mask parameter marked for partitioning. In each iteration of the For Each subsystem, a partition of the filter coefficients is fed to the Transfer Fcn block.

- 1 Open the model `ex_ForEachSubsystem_Partitioning`. Create a mask for the For Each Subsystem block and add an editable mask parameter. Set the name to `FilterCoeffs` and the prompt to `Filter Coefficient Matrix`. For information on how to add a mask parameter, see “Create a Simple Mask”.

- 2 Open the For Each subsystem. Inside the subsystem, open the For Each block dialog box.
- 3 In the **Parameter Partition** tab, select the check box next to the **FilterCoeffs** parameter to enable partitioning of this parameter. Keep the **Partition Width** and **Partition Dimension** parameters at their default value of 1.

- 4 Double-click the For Each Subsystem block and enter your filter coefficient matrix, having one row of filter coefficients for each input signal. For example, enter [0.0284 0.2370 0.4692 0.2370 0.0284; -0.0651 0 0.8698 0 -0.0651; 0.0284 -0.2370 0.4692 -0.2370 0.0284] to implement different fourth-order filters for each input signal.
- 5 In the For Each subsystem, double-click the Transfer Fcn block and enter **FilterCoeffs** for the **Denominator Coefficients** parameter. This setting causes the block to get its coefficients from the mask parameter.

The For Each subsystem slices the input parameter into horizontal partitions of width 1, which is equivalent to one row of coefficients. The parameter of coefficients transforms from a single array:

Partition dimension set to 1

0.0284	0.2370	0.4692	0.2370	0.0284
-0.0651	0.0000	0.8698	0.0000	-0.0651
0.0284	-0.2370	0.4692	-0.2370	0.0284

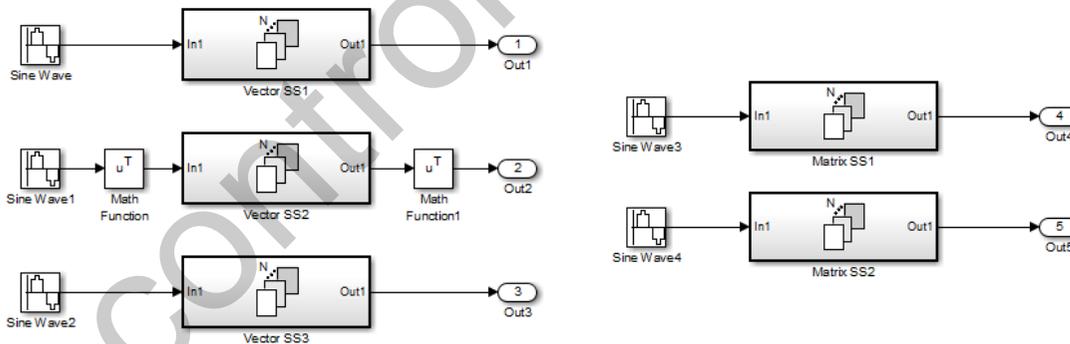

into three rows of parameters:

0.0284	0.2370	0.4692	0.2370	0.0284
-0.0651	0.0000	0.8698	0.0000	-0.0651
0.0284	-0.2370	0.4692	-0.2370	0.0284

### Improved Code Reuse Using For Each Subsystems

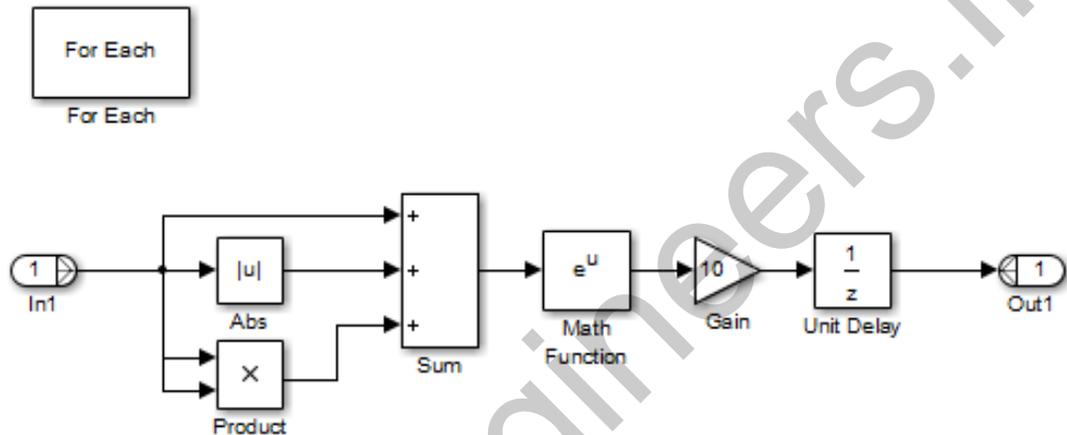

This example shows how you can improve code reuse when you have two or more identical For Each subsystems. Consider the following model, rtwdemo\_foreachreuse.

Reusing Functions with Different Input Sizes

The intent is for the three subsystems — Vector SS1, Vector SS2, and Vector SS3 — to apply the same processing to each scalar element of the vector signal at their respective inputs. Because these three subsystems perform the same processing, it is desirable for

them to produce a single shared Output (and Update) function for all three subsystems in the code generated for this model. For example, the Vector SS3 subsystem contains the following blocks:

To generate a single shared function for the three subsystems, the configuration of the partitioning they perform on their input signals must be the same. For Vector SS1 and Vector SS3, this configuration is straightforward because you can set the partition dimension and width to 1. However, in order for Vector SS2 to also partition its input signal along dimension 1, you must insert a Math Function block to transpose the 1-by-8 row vector into an 8-by-1 column vector. You can then convert the output of the subsystem back to a 1-by-8 row vector using a second Math Function block set to the transpose operator.

If you press **Ctrl+B** to generate code, the resulting code uses a single Output function. This function is shared by all three For Each Subsystem instances.

```

/*
 * Output and update for iterator system:
 *   '<Root>/Vector SS1'
 *   '<Root>/Vector SS2'
 *   '<Root>/Vector SS3'
 */
void VectorProcessing(int32_T NumIters, const real_T rtu_In1[],
                    real_T rty_Out1[],
                    rtDW_VectorProcessing *localDW)
    
```

The function has an input parameter `NumIters` that indicates the number of independent scalars that each For Each Subsystem is to processes. This function is called three times with the parameter `NumIters` set to 10, 8, and 7 respectively.

The remaining two subsystems in this model show how reusable code can also be generated for matrix signals that are processed using the For Each Subsystem block. Again, pressing **Ctrl+B** to generate the code provides code reuse of a single function.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

For Each

“Repeat an Algorithm Using a For Each Subsystem”

“Log Signals in For Each Subsystems”

**Introduced in R2010a**

## For Iterator

Repeatedly execute contents of subsystem at current time step until iteration variable exceeds specified iteration limit

## Library

Ports & Subsystems

## Description

The For Iterator block, when placed in a subsystem, repeatedly executes the contents of the subsystem at the current time step until an iteration variable exceeds a specified iteration limit. You can use this block to implement the block diagram equivalent of a for loop in the C programming language.

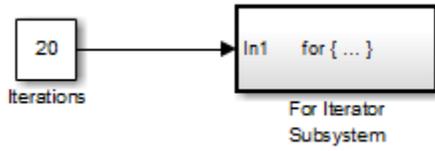

The output of a For Iterator subsystem can not be a function-call signal. Simulink software will display an error message if the simulation is run or the diagram updated.

The block's parameter dialog allows you to specify the maximum value of the iteration variable or an external source for the maximum value and an optional external source for the next value of the iteration variable. If you do not specify an external source for the next value of the iteration variable, the next value is determined by incrementing the current value:

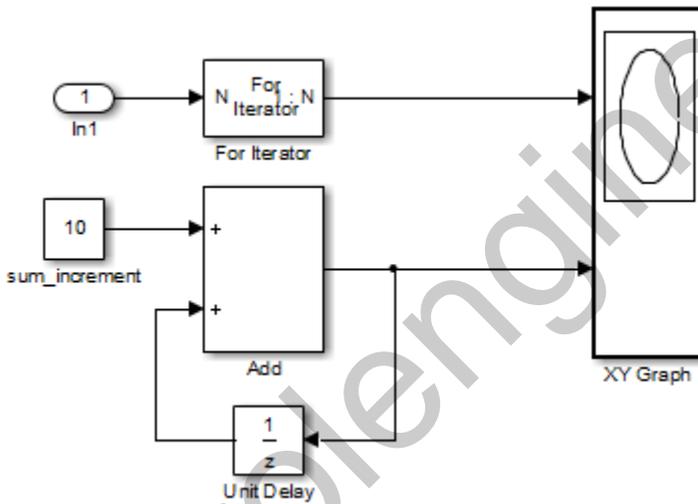

$$i_{n+1} = i_n + 1$$

Suppose that you have the following model:

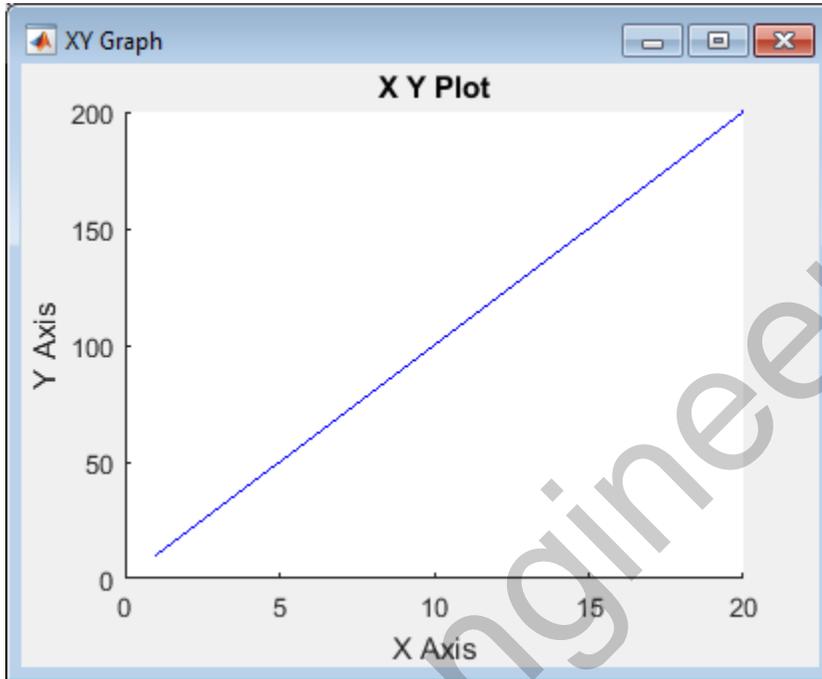

1 Blocks – Alphabetical List

For 20 iterations, the For Iterator block increments a value by 10 at each time step:

The following figure shows the result.

The For Iterator subsystem in this example is equivalent to the following C code.

```

sum = 0;
iterations = 20;
sum_increment = 10;
for (i = 0; i < iterations; i++) {
    sum = sum + sum_increment;
}
    
```

---

**Note** Placing a For Iterator block in a subsystem makes it an atomic subsystem if it is not already an atomic subsystem.

---

## Data Type Support

The following rules apply to the data type of the number of iterations (N) input port:

- The input port accepts data of mixed numeric types.

- If the input port value is noninteger, it is first truncated to an integer.
- Internally, the input value is cast to an integer of the type specified for the iteration variable output port.
- If no output port is specified, the input port value is cast to type `int32`.
- If the input port value exceeds the maximum value of the output port's type, it is truncated to that maximum value.

Data output for the iterator value can be selected as `double`, `int32`, `int16`, or `int8` in the block parameters dialog box.

The following rules apply to the iteration variable input port:

- It can appear only if the iteration variable output port is enabled.
- The data type of the iteration variable input port is the same as the data type of the iteration variable output port.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### States when starting

Set this field to `reset` if you want the states of the For subsystem to be reinitialized before the first iteration at each time step. Otherwise, set this field to `held` (the default) to make sure that these subsystem states retain their values from the last iteration at the previous time step.

### Iteration limit source

If you set this field to `internal`, the value of the **Iteration limit** field determines the number of iterations. If you set this field to `external`, the signal at the For Iterator block's N port determines the number of iterations. The iteration limit source must reside outside the For Iterator subsystem.

### Iteration limit

Set the number of iterations by specifying a number or a named constant. This field appears only if you selected `internal` for the **Iteration limit source** field. This parameter supports storage classes. You can define the named constant in the base workspace of the Model Explorer as a Simulink.Parameter object of the built-in storage class `Define (custom)` type. For more information, see “Apply a Custom

Storage Class from the Simulink Package Using Data Objects” (Embedded Coder) in the Embedded Coder documentation.

### Set next i (iteration variable) externally

This option can be selected only if you select the **Show iteration variable** option. If you select this option, the For Iterator block displays an additional input for connecting an external iteration variable source. The value of the input at the current iteration is used as the value of the iteration variable at the next iteration.

### Show iteration variable

If you select this check box, the For Iterator block outputs its iteration value.

### Index mode

If you set this field to **Zero-based**, the iteration number starts at zero. If you set this field to **One-based**, the iteration number starts at one.

### Iteration variable data type

Set the type for the iteration value output from the iteration number port to **double**, **int32**, **int16**, or **int8**.

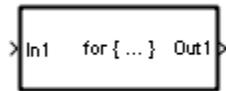

## Characteristics

Direct Feedthrough	No
Sample Time	Inherited from driving blocks
Scalar Expansion	No
Dimensionalized	No
Zero Crossing	No

**Introduced before R2006a**

## For Iterator Subsystem

Represent subsystem that executes repeatedly during simulation time step

### Library

Ports & Subsystems

### Description

The For Iterator Subsystem block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem that executes repeatedly during a simulation time step.

For more information, see the For Iterator block in the online Simulink block reference and “Use Control Flow Logic” in the Simulink documentation.

When using simplified initialization mode, you cannot place any block needing elapsed time within an Iterator Subsystem. In simplified initialization mode, Iterator subsystems do not maintain elapsed time, so Simulink will report an error if any such block (such as the Discrete-Time Integrator block) is placed within the subsystem. For more information on simplified initialization modes, see “Underspecified initialization detection”.

### Characteristics

Controlengineers.ir

## From

Accept input from Goto block

## Library

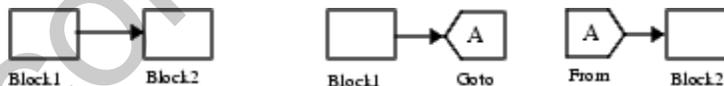

Signal Routing

## Description

The From block accepts a signal from a corresponding Goto block, then passes it as output. The data type of the output is the same as that of the input from the Goto block. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them. To associate a Goto block with a From block, enter the Goto block's tag in the **Goto Tag** parameter.

A From block can receive its signal from only one Goto block, although a Goto block can pass its signal to more than one From block.

This figure shows that using a Goto block and a From block is equivalent to connecting the blocks to which those blocks are connected. In the model at the left, Block1 passes a signal to Block2. That model is equivalent to the model at the right, which connects Block1 to the Goto block, passes that signal to the From block, then on to Block2.

The visibility of a Goto block tag determines the From blocks that can receive its signal. For more information, see Goto and Goto Tag Visibility. The block indicates the visibility of the Goto block tag:

- A local tag name is enclosed in brackets ([]).

- A scoped tag name is enclosed in braces ({}).
- A global tag name appears without additional characters.

The From block supports signal label propagation.

## Data Type Support

The From block outputs real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Goto Tag

The tag of the Goto block that forwards its signal to this From block.

To change the tag, select a new tag from this control's drop-down list. The drop-down list displays the Goto tags that the From block can currently see. An item labeled **<More Tags . . . >** appears at the end of the list the first time you display the list in a Simulink session. Selecting this item causes the block to update the tags list to include the tags of Goto blocks residing in library subsystems referenced by the model containing this From block. Simulink software displays a progress bar while building the list of library tags. Simulink software saves the updated tags list for the duration of the Simulink session or until the next time you select the adjacent **Update Tags** button. You need to update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box. To find the Goto block, use the **Goto Source** hyperlink.

### Update Tags

Updates the list of tags visible to this From block, including tags residing in libraries referenced by the model containing this From block.

### Goto Source

Path of the Goto block connected to this From block. Clicking the path displays and highlights the Goto block.

### Icon Display

Specifies the text to display on the From block's icon. The options are the block's tag, the name of the signal that the block represents, or both the tag and the signal name.

## Examples

The following models show how to use the From block:

- `sldemo_auto_climatecontrol`
- `sldemo_hardstop`

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from the block driving the Goto block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## From Dataflow

Close a dataflow region and restore simulation to time-based simulation

**Library:** DSP System Toolbox / Dataflow

### Description

A From Dataflow block provides an output signal from a dataflow region where simulation is data-driven and restores the simulation to time-based simulation. Blocks and signal lines inside of a dataflow region have no sample time, therefore blocks execute only when they have sufficient data available.

Data-driven simulation makes dataflow regions amenable to multithreaded execution, especially in applications with streaming computation intensive signal processing workloads. Dataflow regions execute parts of the region with no data dependencies in parallel.

Use this block to specify the design latency of the region. The pipelining delay added to the model generates concurrency by breaking data dependencies between blocks. Fewer data dependencies gives Simulink more flexibility in assigning blocks to threads and generally allows Simulink to use more threads.

### Ports

#### Input

##### Port\_1 — Input signal

data-driven signal

Data-driven signal to be converted to time-based signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### Output

##### Port\_2 — Output signal

time-based signal

Time-based signal that has been converted from a data-driven signal. This output signal is no longer part of a dataflow region in the model.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point` | `enumerated` | `bus`

## Parameters

### **Design Latency (Sample Periods) — Latency introduced by the software**

positive scalar

Latency introduced by the software into the design. This latency indicates the amount of pipelining available to Simulink to use to improve the throughput of a dataflow region. After model compilation, the block recommends a value for this parameter if the current specified value is different from the recommended value. All From Dataflow blocks from the same dataflow region must specify the same design latency.

### **Initial condition — Initial value of the output signal**

Specify initial values for the output signal in the time-based region of the model until the data provided to the domain has traversed through the set of pipeline delays.

## From File

Load data from MAT-file

## Library

Sources

## Description

The From File block loads data from a MAT-file to a model and outputs the data as a signal. The data is a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

The From File block icon shows the name of the MAT-file that supplies the data to the block.

You can have multiple From File blocks that load from the same MAT-file.

The supported MAT-file versions are Version 7.0 or earlier and Version 7.3. The From File block incrementally loads data from Version 7.3 files.

You can specify how the data is loaded, including:

- Sample time
- How to handle data for missing data points
- Whether to use zero-crossing detection

For more information, see “Load Data Using the From File Block”.

## Code Generation Requirements

For a From File block, generating code that builds ERT or GRT targets or uses SIL or PIL simulation modes requires that:

- The MAT-file contains a nonempty, finite, real matrix with at least two rows.
  - Use a data type of **double** for the matrix.
  - Do not include any NaN, Inf, or -Inf elements in the matrix.
- In the From File block parameters dialog box:
  - Set the **Data extrapolation before first data point** and **Data extrapolation after last data point** parameters to **Linear extrapolation**.
  - Set the **Data interpolation within time range** parameter to **Linear interpolation**.
  - Clear the **Enable zero-crossing detection** parameter.

## Data Type Support

For MATLAB `timeseries` data, the From File block loads real or complex signal data of any data type that Simulink supports. Fixed-point data cannot have a word length that exceeds 32 bits. The From File block supports loading nonvirtual bus signals in `timeseries` format.

For array data, the From File block loads only double signal data.

For more information, see “Create Data for a From File Block”.

## Parameters

### File name

The path or file name of the MAT-file that contains the input data. Specify a path or file name in one of these ways:

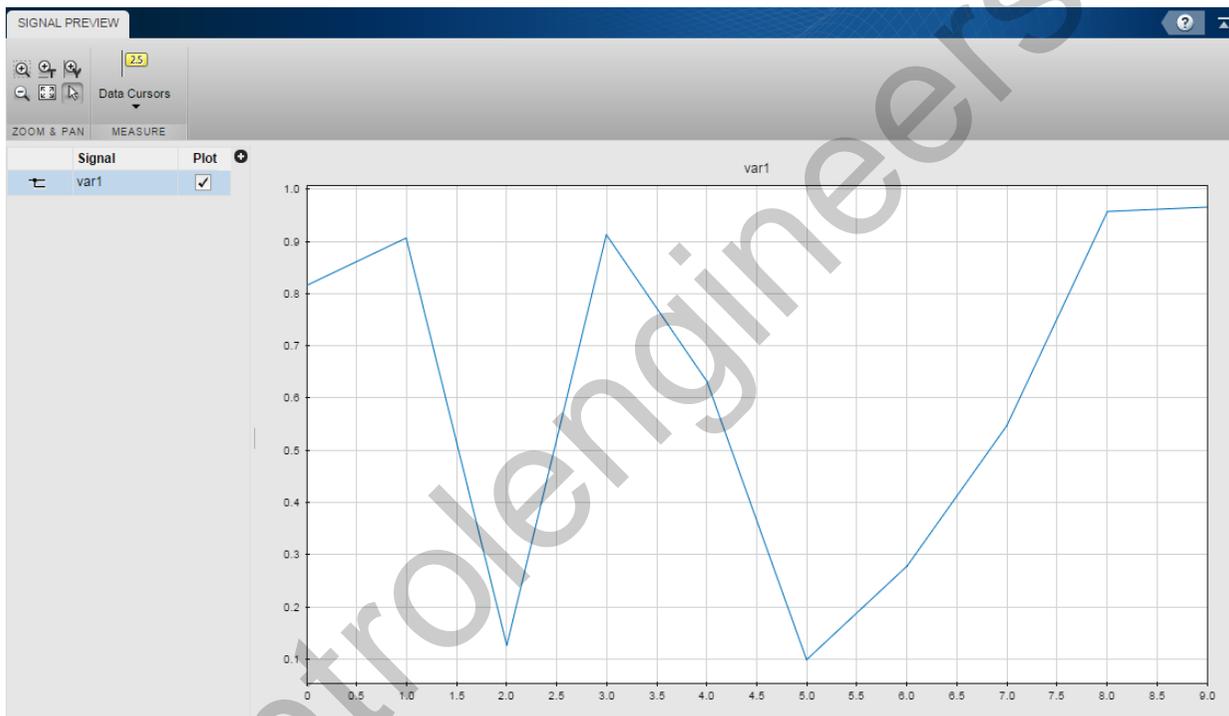

- Browse to a folder that contains a valid MAT-file.

On UNIX<sup>®</sup> systems, the path name can start with a tilde (~) character, which means your home folder.

- Enter the path for the file in the text box.

The default file name is `untitled.mat`. If you specify a file name without path information, Simulink loads the file in the current folder or on the MATLAB path. (To determine the current folder, at the MATLAB command prompt enter `pwd`.)

To preview the data in the Signal Preview window, click the view button .

Use the Signal Preview window to plot and inspect data.

- 1 To plot the signal, select the check box next to the signal. If the format is a bus, click the expander  to see and select the elements of the bus.
- 2 Explore the plots by using the **Measure** and **Zoom & Pan** sections of the toolbar.
  - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the line.

- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Zoom Action	Button
Zoom in along the time and data value axes.	
Zoom in along the time axis. Click the button. On the graph, drag the cursor to select an area to enlarge.	
Zoom in along the data value axis. Click the button. On the graph, drag the cursor to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. Click the button. Click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Click the button. On the graph, drag the cursor to the area of the graph that you want to view.	

### Command-Line Information

**Parameter:** FileName

**Type:** character vector

**Default:** 'untitled.mat'

### Output data type

The data type for the data that the From File block outputs. For nonbus types, you can use `Inherit: auto` to skip any data type verification. If you specify an output data type, then the From File block verifies that the data in the file matches the specified data type. For more information, see “Control Signal Data Types”.

- `Inherit: auto` — Default
- `double`
- `single`

- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean
- fixdt(1,16,0) — Data type is fixed point (1,16,0).
- fixdt(1,16,2^0,0) — Data type is fixed point (1,16,2^0,0).
- Enum: <class\_name> — Data type is enumerated.
- Bus: <bus\_object> — Data type is a bus object. For details, see the “Using Bus Data” section.
- <data type expression> — The name of a data type object, for example Simulink.NumericType. Do not specify a bus object as the expression.

If you set **Output data type** as a bus object, the bus object must be available when you compile the model. For each signal in bus data, the From File block verifies that data type, dimension, and complexity are the same for the data and for the bus object.

### >> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

### Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

- **Inherit** — Inheritance rule for data types. Selecting **Inherit** enables a second menu and text box. (Default)
- **Built in** — Built-in data types. Selecting **Built in** enables a second menu and text box. Select one of the following choices:
  - double — Default
  - single
  - int8
  - uint8

- int16
- uint16
- int32
- uint32
- boolean
- Fixed point — Fixed-point data types
- Enumerated — Enumerated data types. Selecting Enumerated enables a second menu/text box to the right, where you can enter the class name.
- Bus — Bus object. Enables a **Bus object** parameter, where you enter bus object name for defining the structure of the bus. If you create or change a bus object, open the Simulink Bus Editor by clicking **Edit**. For details, see “Create Bus Objects with the Bus Editor”.
- Expression — Expression that evaluates to a data type. Selecting Expression enables a second menu and text box to the right, where you enter the expression. Do not specify a bus object as the expression.

## Sample time

The sample period and offset.

The From File block loads data from a MAT-file, using a sample time that either:

- You specify for the From File block.
- The From File block inherits from the blocks into which the From File block feeds data.

The default sample time is 0, which specifies a continuous sample time. The MAT-file is loaded at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

### Command-Line Information

**Parameter:** SampleTime

**Type:** character vector

**Default:** '0'

## Data extrapolation before first data point

Extrapolation method for a simulation time hit that occurs before the initial time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, linearly extrapolates the value using the first two samples</li> <li>• For <b>Boolean</b> data, outputs the first data value</li> <li>• For a built-in data type other than <b>double</b> or <b>Boolean</b>, the From File block: <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b></li> <li>• Performs linear extrapolation (as described for <b>double</b> data)</li> <li>• Downcasts the extrapolated data value to the original data type</li> </ul> </li> </ul> <p>You cannot use the <b>Linear extrapolation</b> option with enumerated (<b>enum</b>) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses <b>enum</b> data, then you cannot use the <b>Linear extrapolation</b> option.</p>
Hold first value	Uses the first data value in the file
Ground value	<p>Uses a value that depends on the data type of MAT-file sample data values:</p> <ul style="list-style-type: none"> <li>• Fixed-point data types — uses the ground value</li> <li>• Numeric types other than fixed point — uses 0</li> <li>• <b>Boolean</b> — uses <b>false</b></li> <li>• Enumerated data types — uses default value</li> </ul>

#### Command-Line Information

**Parameter:** ExtrapolationBeforeFirstDataPoint

**Type:** character vector

**Value:** 'Linear extrapolation' | 'Hold first value' | 'Ground value'

**Default:** 'Linear extrapolation'

## Data interpolation within time range

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the MAT-file. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From File block interpolates using the two corresponding MAT-file samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, linearly interpolates the value using the two corresponding samples</li> <li>• For <b>Boolean</b> data, uses <b>false</b> for the first half of the sample and <b>true</b> for the second half.</li> <li>• For a built-in data type other than <b>double</b> or <b>Boolean</b>, the From File block:                             <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b></li> <li>• Performs linear interpolation, as described for <b>double</b> data</li> <li>• Downcasts the interpolated value to the original data type</li> </ul> </li> </ul> <p>You cannot use the <b>Linear interpolation</b> option with enumerated (<b>enum</b>) data. All signals in a bus use the same interpolation setting. If any signal in a bus uses <b>enum</b> data, then you cannot use the <b>Linear interpolation</b> option.</p>
Zero order hold	Uses the data from the first of the two samples

### Command-Line Information

**Parameter:** InterpolationWithinTimeRange

**Type:** character vector

'Linear interpolation' | 'Zero order hold'

**Default:** 'Linear interpolation'

## Data extrapolation after last data point

The extrapolation method for a simulation time hit that occurs after the last time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, extrapolates the value using the last two samples.</li> <li>• For <b>Boolean</b> data, outputs the first data value.</li> <li>• For built-in data types other than double or <b>Boolean</b>:           <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b></li> <li>• Performs linear extrapolation, as described for <b>double</b> data</li> <li>• Downcasts the extrapolated value to the original data type</li> </ul> </li> </ul> <p>You cannot use the <b>Linear extrapolation</b> option with enumerated (<b>enum</b>) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses <b>enum</b> data, then you cannot use the <b>Linear extrapolation</b> option.</p>
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of MAT-file sample data values:</p> <ul style="list-style-type: none"> <li>• Fixed-point data types — uses the ground value</li> <li>• Numeric types other than fixed point — uses 0</li> <li>• <b>Boolean</b> — uses <b>false</b></li> <li>• Enumerated data types — uses default value</li> </ul>

### Command-Line Information

**Parameter:** ExtrapolationAfterLastDataPoint

**Type:** character vector

'Linear extrapolation' | 'Hold last value' | 'Ground value'

**Default:** 'Linear extrapolation'

## Enable zero-crossing detection

Enables zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate a discontinuity in time stamps, without resorting to excessively small time steps. “Zero-crossing” represents a discontinuity.

For the From File block, zero-crossing detection occurs only at time stamps in the file. Simulink examines only the time stamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at those time stamps. For example, suppose that the input array has this data:

```
time:      0 1 2 2 3
signal:    2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

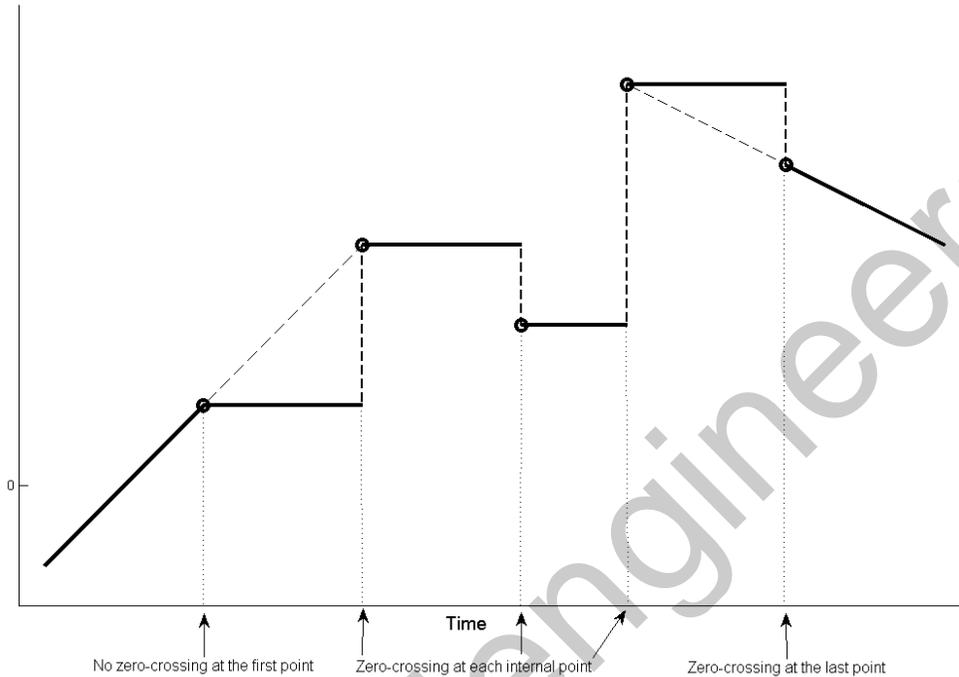

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The From File block determination of when zero-crossing occurs depends on the time stamp.

Time Stamp	Setting
First	<b>Data extrapolation before first data point</b> is set to Ground value.
Between first and last	<b>Data interpolation within time range</b> is set to Zero-order hold.
Last	One or both of these settings occur: <ul style="list-style-type: none"> <li>• <b>Data extrapolation after last data point</b> is set to Ground value.</li> <li>• <b>Data interpolation within time range</b> is set to Zero-order hold.</li> </ul>

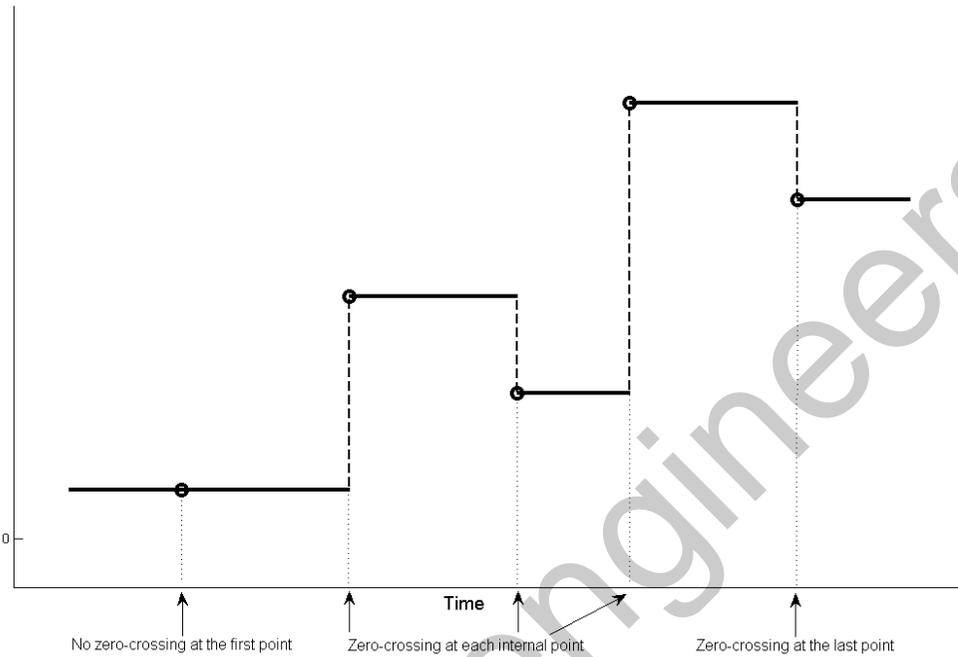

This figure illustrates zero-crossing detection for data accessed by a From File block that has the following settings:

- **Data extrapolation before first data point** — Linear extrapolation
- **Data interpolation within time range** (for internal points) — Zero order hold
- **Data extrapolation after last data point** — Linear extrapolation

This figure is another illustration of zero-crossing detection for data accessed by a From File block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** — Hold first value
- **Data interpolation within time range** — Zero order hold
- **Data extrapolation after last data point** — Hold last value

## Examples

### From File Block Loading Timeseries Data

Create a MATLAB® timeseries object with time and signal values. Save the timeseries object to a MAT-file and load into a model using a From File block.

Create an array with the time and signal data, specifying signal data for 10 time steps.

```

t = .1*(1:10);
d = .2*(1:10);
x = [t;d];
    
```

Create a MATLAB timeseries object.

```

ts = timeseries(x(2:end,:),x(1,:))
    
```

timeseries

Common Properties:

```
Name: 'unnamed'
Time: [10x1 double]
TimeInfo: tsdata.timemetadata
Data: [1x1x10 double]
DataInfo: tsdata.datametadata
```

Save the `timeseries` object in a Version 7.3 MAT-file.

```
save('mySignals','ts','-v7.3')
```

Add a From File block and set the **File name** parameter of that block to `mySignals.mat`.

Simulate the model. The Scope block reflects the data loaded from the `mySignals.mat` file.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## From Spreadsheet

Read data from spreadsheet

## Library

Sources

## Description

The From Spreadsheet block reads data from Microsoft Excel® (all platforms) or CSV (Microsoft Windows® platform with Microsoft Office installed only) spreadsheets and outputs the data as a signal.

The From Spreadsheet icon displays the spreadsheet file name and sheet name specified in the block **File name** and **Sheet name** parameters.

## Storage Formats

The data that the From Spreadsheet block reads from a spreadsheet must be appropriately formatted.

For Microsoft Excel spreadsheets:

- The From Spreadsheet block interprets the first row as a signal name. If you do not specify a signal name, the From Spreadsheet block assigns a default one with the format **Signal #**, where # increments with each additional unnamed signal.
- The From Spreadsheet block interprets the first column as time. In this column, the time values must monotonically increase.
- The From Spreadsheet block interprets the remaining columns as signals.

This example shows an acceptably formatted Microsoft Excel spreadsheet. The first column is Time and the first row contains signal names. Each worksheet contains a signal group.

1	Time	DC In	Trigger	AC In	
2	0	1	2	3	
3	1	2	3	4	
4	2	3	4	5	
5	3	4	5	6	
6	4	5	6	7	
7	5	6	7	8	
8	6	7	8	9	
9	7	8	9	10	
10	8	9	10	11	
11	9	10	11	12	
12	10	11	12	13	
13	11	12	13	14	
14	12	13	14	15	
15	13	14	15	16	
16	14	15	16	17	
17	15	16	17	18	
18					

Group1 Group2 Group3

For CSV text files (Microsoft platform with Microsoft Office installed only):

- The From Spreadsheet block interprets the first column as time. In this column, the time values must increase.
- The From Spreadsheet block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The From Spreadsheet block interprets each file as one signal group.

This example shows an acceptably formatted CSV file. The contents represent one signal group.

## Block Behavior During Simulation

The From Spreadsheet block incrementally reads data from the spreadsheet during simulation.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-686. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-683.

## Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps

If the simulation time hit does not have a corresponding spreadsheet time stamp, the From Spreadsheet block output depends on:

- Whether the simulation time hit occurs before the first time stamp, within the range of time stamps, or after the last time stamp
- The interpolation or extrapolation methods that you select
- The data type of the spreadsheet data

For details about interpolation and extrapolation options, see the descriptions of the following parameters in “Parameters and Dialog Box”:

- **Data extrapolation before first data point**

- **Data interpolation within time range**
- **Data extrapolation after last data point**

Sometimes the spreadsheet includes two or more data values that have the same time stamp. In such cases, the From Spreadsheet block action depends on when the simulation time hit occurs, relative to the duplicate time stamps in the spreadsheet.

For example, suppose that the spreadsheet contains this data. Three data values have a time stamp value of 2.

```
time stamps:    0 1 2 2 2 3 4
data values:    2 3 6 4 9 1 5
```

The table describes the From Spreadsheet block output.

Simulation Time, Relative to Duplicate Time Stamp Values in Spreadsheet	From Spreadsheet Block Action
Before the duplicate time stamps	Performs the same actions as when the time stamps are distinct, using the first of the duplicate time stamp values as the basis for interpolation. (In this example, the time stamp value is 6.)
At or after the duplicate time stamps	Performs the same actions as when the times stamps are distinct, using the last of the duplicate time stamp values as the basis for interpolation. (In this example, that time stamp value is 9.)

## Rounding Mode

The From Spreadsheet block rounds positive and negative numbers toward negative infinity. This mode is equivalent to the MATLAB `floor` function.

## Saturation on Integer Overflow

For data type conversion, the From Spreadsheet block deals with saturation overflow by wrapping to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to  $-126$ .

## Code Generation Requirements

Simulating in accelerator, rapid accelerator, or model reference accelerator mode behaves the same way, and has the same requirements, as simulating in normal mode.

The From Spreadsheet block does not support generating code that involves building ERT or GRT targets, or using SIL or PIL simulation modes.

## Data Type Support

The From Spreadsheet block supports these data types:

- Inherit: auto — Default
- double
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- Boolean
- fixdt(1,16,0) — Data type is fixed point (1,16,0).
- fixdt(1,16,2^0,0) — Data type is fixed point (1,16,2^0,0).
- Enum: <class\_name> — Data type is enumerated.
- data type expression — The name of a data type object, for example Simulink.NumericType. Do not specify a bus object as the expression.

The From Spreadsheet block accepts data type specifications at a block level.

If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: Auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as boolean.

## Parameters

### File name

Enter full path and file name of a spreadsheet file.

This block supports non-English full paths and file names only on Microsoft platforms.

### Settings

**Default:** untitled.xlsx

### Command-Line Information

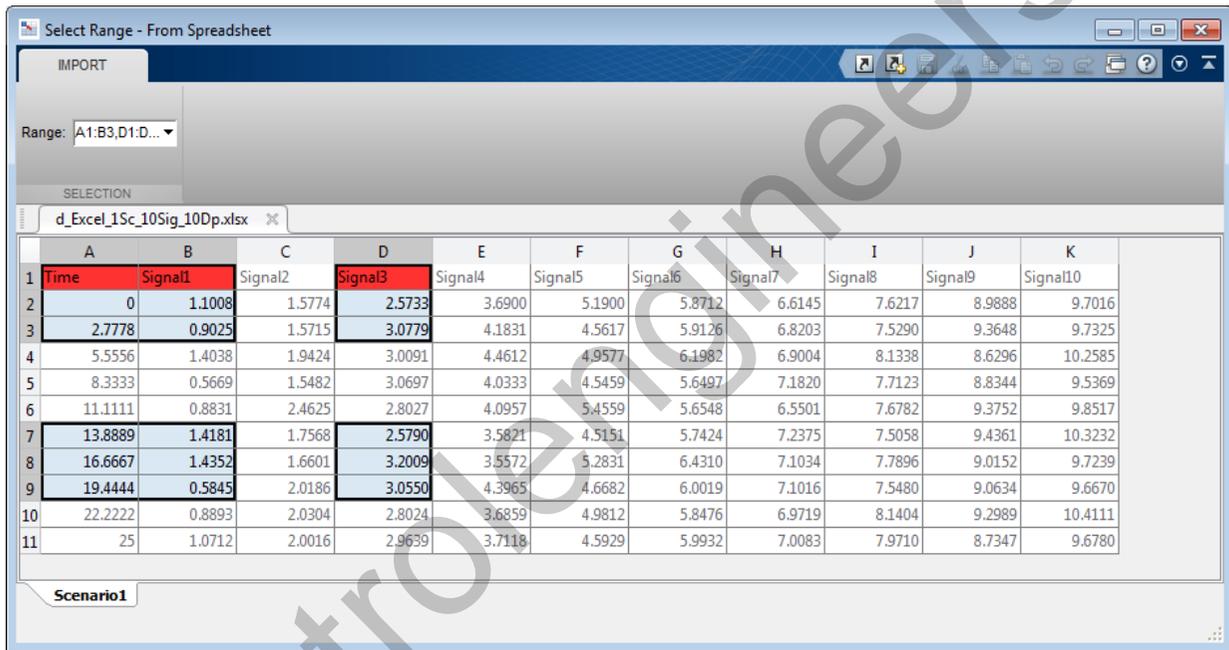

FileName	character vector
----------	------------------

Controlengineers.ir

## Sheet name

Enter the name of the sheet in the spreadsheet. You can type the sheet name in this edit box, or select the sheet name after you open the sheet.

To open the sheet, click . In the sheet, you can select the range of data by dragging over the desired range of values.

The screenshot shows the 'Select Range - From Spreadsheet' dialog box. The 'Range' field is set to 'A1:B3,D1:D...'. The spreadsheet data is as follows:

	A	B	C	D	E	F	G	H	I	J	K
1	Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
2	0	1.1008	1.5774	2.5733	3.6900	5.1900	5.8712	6.6145	7.6217	8.9888	9.7016
3	2.7778	0.9025	1.5715	3.0779	4.1831	4.5617	5.9126	6.8203	7.5290	9.3648	9.7325
4	5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
5	8.3333	0.5669	1.5482	3.0697	4.0333	4.5459	5.6497	7.1820	7.7123	8.8344	9.5369
6	11.1111	0.8831	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
7	13.8889	1.4181	1.7568	2.5790	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
8	16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
9	19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
10	22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
11	25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

Alternatively, you can select the range of data by specifying the range of values in the **Range** parameter.

### Settings

**Default:** Sheet1

### Command-Line Information

SheetName	character vector
-----------	------------------

## Range

To specify the range, use the format *column:row*, with multiple specifications separated by commas. For example, *A1:B3,D1:D3,A7:B9,D7:D9*. If unspecified, or empty, the block automatically detects the used range, which is all the data in the sheet.

A	B	C	D	E	F	G	H	I	J	K
Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
0	1.1008	1.5774	2.5733	3.6900	5.1900	5.8712	6.6145	7.6217	8.9888	9.7016
2.7778	0.9025	1.5715	3.0779	4.1831	4.5617	5.9126	6.8203	7.5290	9.3648	9.7325
5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
8.3333	0.5669	1.5482	3.0697	4.0333	4.5459	5.6497	7.1820	7.7123	8.8344	9.5369
11.1111	0.8831	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
13.8889	1.4181	1.7568	2.5790	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

If the selections overlap, the block resolves the selection information as appropriate. For example, if you specify multiple ranges that overlap, such as *A1:B4,B1:E7*, the block resolves the selection to *A1 to E7*, inclusive.

### Settings

**Default:** Empty

### Command-Line Information

Range	character vector
-------	------------------

## Output data type

The data type for the From Spreadsheet block output. The From Spreadsheet block accepts spreadsheets that contain many data types. However, the block reads the spreadsheet data type as doubles. It then outputs the data type according to the value of **Output data type**.

To allow the block to cast the output data type to match that of the receiving block, use **Inherit: auto**.

For more information, see “Control Signal Data Types”.

### Settings

**Default:** Inherit: auto

Cast output data type to match that of the receive block.

**Inherit: auto**

Cast output data type to match that of the receive block.

**double**

Output data type is **double**.

**single**

Output data type is **single**.

**int8**

Output data type is **int8**.

**uint8**

Output data type is **uint8**.

**int16**

Output data type is **int16**.

**uint16**

Output data type is **uint16**.

**int32**

Output data type is **int32**.

**uint32**

Output data type is `uint32`.

`boolean`

Output data type is `boolean`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Output data type is enumerated, for example, Enum: `Basic Colors`.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

#### Command-Line Information

<code>OutDataTypeStr</code>	character vector — {'Inherit: auto'}   'double'   'single'   'int8'   'uint8'   'int16'   'uint16'   'int32'   'uint32'   'boolean'   'fixdt(1,16,0)'   'fixdt(1,16,2^0,0)'   'Enum: <class name>'
-----------------------------	--

## >> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

Controlengineers.ir

## Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

### Settings

#### Default: Inherit

Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right.

- **Inherit**

Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right.

- **Built in**

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- **double** — Default
- **single**
- **int8**
- **uint8**
- **int16**
- **uint16**
- **int32**
- **uint32**
- **boolean**
- **Fixed point** — Fixed-point data types
- **Enumerated** — Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.
- **Expression** — Expression that evaluates to a data type. Selecting **Expression** enables a second menu/text box to the right, where you enter the expression.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

See “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Sample time

The sample period and offset.

The From Spreadsheet block reads data from a spreadsheet using a sample time that either:

- You specify for the From Spreadsheet block
- The From Spreadsheet block inherits from the blocks into which the From Spreadsheet block feeds data

The default is 0, which specifies a continuous sample time. The spreadsheet is read at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

### Command-Line Information

SampleTime	character vector — {'0'}
------------	--------------------------

## Data extrapolation before first data point

Extrapolation method that Simulink uses for a simulation time hit that is before the first time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, linearly extrapolates the value using the first two samples</li> <li>• For <b>Boolean</b> data, outputs the first data value</li> <li>• For a built-in data type other than <b>double</b> or <b>Boolean</b>: <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b>.</li> <li>• Performs linear extrapolation (as described above for <b>double</b> data).</li> <li>• Downcasts the extrapolated data value to the original data type.</li> </ul> </li> </ul> <p>You cannot use the <b>Linear extrapolation</b> option with enumerated (<b>enum</b>) data.</p>
Hold first value	Uses the first data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> <li>• Fixed-point data types — Uses the ground value</li> <li>• Numeric types other than fixed-point — Uses 0</li> <li>• <b>Boolean</b> — Uses <b>false</b></li> <li>• Enumerated data types — Uses default value</li> </ul>

### Command-Line Information

ExtrapolationBeforeFirstDataPoint	character vector — {'Linear extrapolation'}   'Hold first value'   'Ground value'
-----------------------------------	---

controlengineers.ir

## Data interpolation within time range

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the spreadsheet. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From Spreadsheet block interpolates using the two corresponding spreadsheet samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, linearly interpolates the value using the two corresponding samples</li> <li>• For <b>Boolean</b> data, uses <b>false</b> for the first half of the sample and <b>true</b> for the second half.</li> <li>• For a built-in data type other than <b>double</b> or <b>Boolean</b>: <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b>.</li> <li>• Performs <b>linear</b> interpolation (as described above for <b>double</b> data).</li> <li>• Downcasts the interpolated value to the original data type.</li> </ul> </li> </ul> <p>You cannot use the <b>Linear interpolation</b> option with enumerated (<b>enum</b>) data.</p>
Zero order hold	Uses the data from the first of the two samples

### Command-Line Information

InterpolationWithinTimeRange	character vector — {'Linear interpolation'}   'Zero order hold'
------------------------------	---

## Data extrapolation after last data point

The extrapolation method that Simulink uses for a simulation time hit that is after the last time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> <li>• For <b>double</b> data, extrapolates the value using the last two samples</li> <li>• For <b>Boolean</b> data, outputs the last data value</li> <li>• For a built-in data type other than <b>double</b> or <b>Boolean</b>:                             <ul style="list-style-type: none"> <li>• Upcasts the data to <b>double</b>.</li> <li>• Performs linear extrapolation (as described above for <b>double</b> data).</li> <li>• Downcasts the extrapolated value to the original data type.</li> </ul> </li> </ul> <p>You cannot use the <b>Linear extrapolation</b> option with enumerated (<b>enum</b>) data.</p>
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> <li>• Fixed-point data types — uses the ground value</li> <li>• Numeric types other than fixed-point — uses 0</li> <li>• <b>Boolean</b> — uses <b>false</b></li> <li>• Enumerated data types — uses default value</li> </ul>

### Command-Line Information

ExtrapolationAfterLastDataPoint	character vector — {'Linear extrapolation'}   'Hold last value'   'Ground value'
---------------------------------	--

Controlengineers.ir

## Enable zero-crossing detection

Select to enable zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate accurately a discontinuity, without resorting to excessively small time steps. This section uses “zero-crossing” to represent discontinuities.

For the From Spreadsheet block, zero-crossing detection can only occur at time stamps in the file. Simulink examines only the time stamps, not the data values.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at that time stamp. For example, suppose that the input array has this data:

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For data with nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The block applies the following rules when determining when:

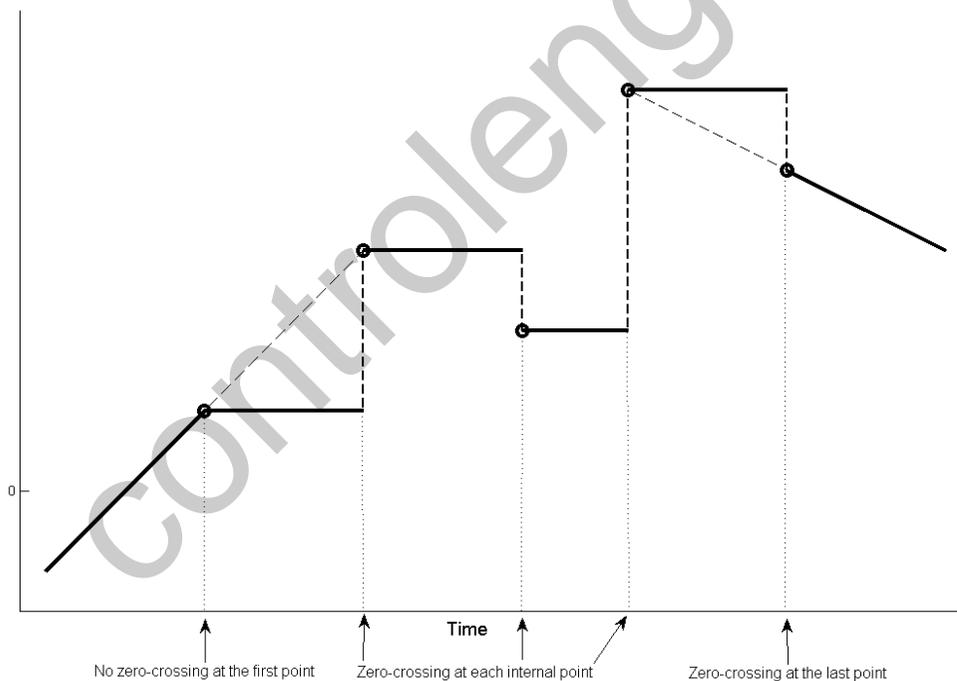

- Zero-crossing occurs for the first time stamp.
- For time stamps between the first and last time stamp.
- For the last time stamp.

Time Stamp	When Zero-Crossing Detection Occurs
First	<b>Data extrapolation before first data point</b> is set to Ground value.
Between first and last	<b>Data interpolation within time range</b> is set to Zero-order hold.

Time Stamp	When Zero-Crossing Detection Occurs
Last	One or both of these settings occur: <ul style="list-style-type: none"> <li>• <b>Data extrapolation after last data point</b> is set to Ground value.</li> <li>• <b>Data interpolation within time range</b> is set to Zero-order hold.</li> </ul>

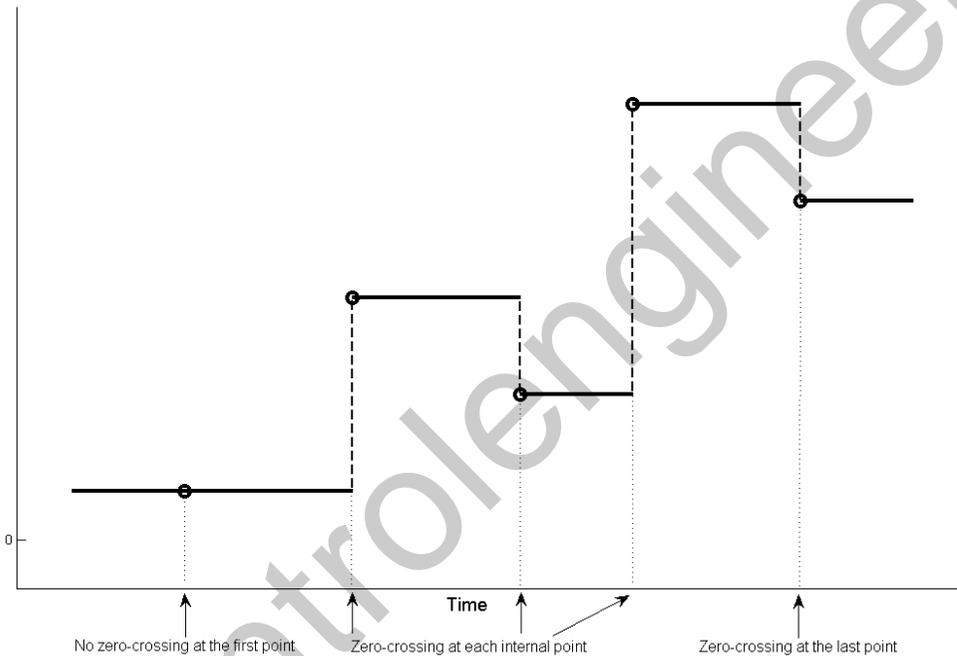

The following figure illustrates zero-crossing detection for data accessed by a From Spreadsheet block that has the following settings:

- **Data extrapolation before first data point** — Linear extrapolation
- **Data interpolation within time range** (for internal points) — Zero order hold
- **Data extrapolation after last data point** — Linear extrapolation

The following figure is another illustration of zero-crossing detection for data accessed by a From Spreadsheet block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** — Hold first value
- **Data interpolation within time range** — Zero order hold
- **Data extrapolation after last data point** — Hold last value

### Command-Line Information

## From Workspace

Load signal data from workspace

## Library

Sources

## Description

The From Workspace block reads signal data from a workspace and outputs the data as a signal.

The From Workspace icon displays the expression specified in the **Data** parameter. For details about how Simulink software evaluates this expression, see “Symbol Resolution”.

You can specify how the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection. For more information, see “Load Data Using the From Workspace Block”.

## Specifying the Workspace Data

In the Block Parameters dialog box of the From Workspace block, in the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB timeseries object
- A structure of MATLAB timeseries objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see “Create Data for a From Workspace Block”.

## Use With Data Dictionary

When you link a model to a data dictionary, you:

- Store design data, which contribute to the fundamental design of the model, in the Design Data section of the dictionary. Design data include numeric variables and `Simulink.Parameter` objects that you use to set block parameter values.
- Store simulation input data, which you use to stimulate and experiment with the model, in the base workspace. Typically, you create simulation input data as MATLAB `timeseries` objects.

For more information about storing variables, objects, and other data that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models”.

- To access design data by using a From Workspace block, store the target variable in the Design Data section of the dictionary and set the **Data** parameter of the block to the name of the variable.
- To access simulation input data, store the target variable in the base workspace and set the **Data** parameter by using a call to the `evalin` function. In the call to `evalin`, specify the `ws` argument as `'base'` so that the block seeks the variable in the base workspace instead of the data dictionary. For example, if the name of the variable is `myTimeseriesObject`, set **Data** to `evalin('base', 'myTimeseriesObject')`.

## Data Type Support

The From Workspace block accepts data from the workspace. The block outputs real or complex signals of any type that Simulink supports, including fixed-point and enumerated data types.

The From Workspace block also accepts a bus object as a data type. To load bus data, use a structure of MATLAB `timeseries` objects. For details, see “Import Bus Data to Top-Level Input Ports”.

Real signals of type `double` can be in any data format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

For additional information, see “Create Data for a From Workspace Block”.

## Parameters

### Data

In the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB timeseries object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see “Specify the Workspace Data”.

#### Command-Line Information

**Parameter:** VariableName

**Type:** character vector

**Default:** 'simin'

### Output data type

The required data type for the data for the workspace variable that the From Workspace block loads. For non-bus types, to skip any data type verification, you can use `Inherit: auto`. For more information, see “Control Signal Data Types”.

To load bus data, use a structure of MATLAB timeseries objects. For details, see “Import Bus Data to Top-Level Input Ports”.

- `Inherit: auto` — Default.
- `double`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`

- int32
- uint32
- boolean
- fixdt(1,16,0) — Data type is fixed point (1,16,0).
- fixdt(1,16,2^0,0) — Data type is fixed point (1,16,2^0,0).
- Enum: <class\_name> — Data type is enumerated, for example, Enum: Basic Colors.
- Bus: <bus\_object> — Data type is a bus object.
- <data type expression> — The name of a data type object, for example Simulink.NumericType. Do not specify a bus object as the expression.

### Command-Line Information

**Parameter:** OutDataTypeStr

**Type:** character vector

'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16'  
 | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' |  
 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

**Default:** 'Inherit: auto'

### >> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

### Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

- **Inherit** — Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right. (Default)
- **Built in** — Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:
  - double — Default
  - single
  - int8
  - uint8

- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`
- **Fixed point** — Fixed-point data types
- **Enumerated** — Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.
- **Bus object** — Bus object. Selecting **Bus** enables a **Bus object** parameter, where you enter the name of a bus object that you want to use to define the structure of the bus. To create or change a bus object, click **Edit** (to the right of the **Bus object** field) to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.
- **Expression** — Expression that evaluates to a data type. Selecting **Expression** enables a second menu/text box to the right, where you enter the expression. Do not specify a bus object as the expression.

## Sample time

Sample rate of loaded data. For details, see “Specify Sample Time”.

### Command-Line Information

**Parameter:** `SampleTime`

**Type:** character vector

**Default:** `'0'`

## Interpolate data

To have the block linearly interpolate at time hits for which no corresponding workspace data exist, select this option. Otherwise, the current output equals the output at the most recent time for which data exists.

The From Workspace block interpolates by using the two corresponding workspace samples:

- For `double` data, linearly interpolates the value by using the two corresponding samples

- For **Boolean** data, uses **false** for the first half of the time between two time values and **true** for the second half
- For a built-in data type other than **double** or **Boolean**:
  - Upcasts the data to **double**
  - Performs linear interpolation (as described for **double** data)
  - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (**enum**) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

#### Command-Line Information

**Parameter:** Interpolate

**Type:** character vector

'off' | 'on'

**Default:** 'on'

### Enable zero-crossing detection

If you select the **Enable zero-crossing detection** parameter, then when the input array contains multiple entries for the same time hit, Simulink detects a zero crossing. For example, suppose that the input array has this data:

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, there is a zero crossing from input signal discontinuity. For more information, see “Zero-Crossing Detection”.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

**Command-Line Information**

**Parameter:** ZeroCross

**Type:** character vector

'off' | 'on'

**Default:** 'on'

**Form output after final data value by**

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

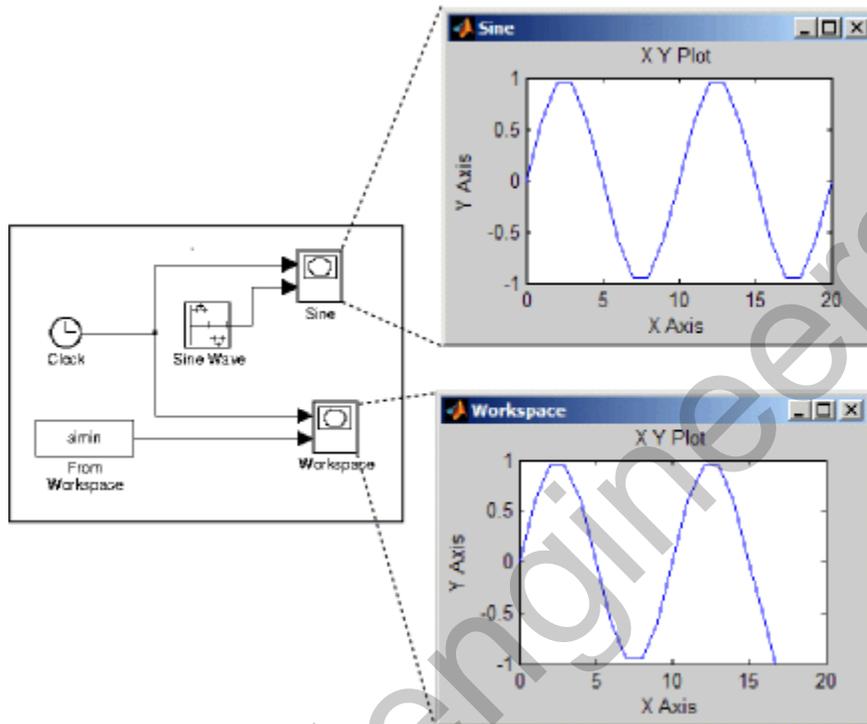

This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
<b>Extrapolation</b>	On	Extrapolated from final data value
	Off	Error
<b>Setting to zero</b>	On	Zero
	Off	Zero
<b>Holding final value</b>	On	Final value from workspace
	Off	Final value from workspace
<b>Cyclic repetition</b>	On	Error
	Off	Repeated from workspace if the workspace data is in structure-without-time format. Error otherwise.

For example, the block uses the last two known data points to extrapolate data points that occur after the last known point if you:

- Select **Interpolate data**.
- Set **Form output after final data value by** to Extrapolation.

Consider this model.

The From Workspace block reads data from the workspace. The data consists of the output of the Simulink Sine block sampled at one-second intervals. The workspace contains the first 16 samples of the output. The top and bottom X-Y plots display the output of the Sine Wave and From Workspace blocks, respectively, from 0 to 20 seconds. The straight line in the output of the From Workspace block reflects the linear extrapolation of missing data points at the end of the simulation.

#### Command-Line Information

**Parameter:** OutputAfterFinalValue

**Type:** character vector

'Extrapolation' | 'Setting to zero' | 'Holding final value' |  
'Cyclic repetition'

**Default:** 'Extrapolation'

## Examples

With the From Workspace block, you can read 1-D and 2-D signals into Simulink. The From Workspace block does not read n-D signals into Simulink.

### Read 1-D Signals in Array Format

Create two signals  $x$  and  $y$  with a time vector  $t$ . Import the values into Simulink with an array.

- 1 In the MATLAB Command Window, enter:

```
t = 0.2 * [0:49]';
x = sin(t);
y = 10*sin(t);
```

The time vector must be a column vector.

- 2 Add a From Workspace block to your model.
- 3 For the From Workspace block, in **Data** parameter, enter the array  $[t, x, y]$ .

### Read 1-D Signals in Structure Format

Create two signals  $x$  and  $y$  with a time vector  $t$ . Import the values into Simulink with a structure.

- 1 In the MATLAB Command Window, enter:

```
t = 0.2 * [0:49]';
x = sin(t);
y = 10*sin(t);
wave.time = t;
wave.signals.values = [x,y];
wave.signals.dimensions =2;
```

The time vector must be a column vector. The `signals.dimensions` field for the signal is a scalar corresponding to the number of columns in the `signals.values` field.

- 2 Add a From Workspace block to your model.
- 3 In the From Workspace block parameters dialog box, in the **Data** field, enter the structure name.

## Use Sample Time from Model

If you do not have a time vector, you can define the sample time in your model.

- 1 In the MATLAB Command Window, enter  

```
wave.time = [];
```
- 2 In the From Workspace block parameters dialog box, in the **Sample time** field, enter a time interval. For example, enter 0.2. Clear the **Interpolate data** check box.
- 3 In the **Form output after final data value by**, select **Setting to zero**, **Holding final value**, or **Cyclic repetition**. Do not select **Extrapolation**.

## Read 2-D Signals in Structure Format

To load 2-D signals from the MATLAB workspace into Simulink, you must have the signals in a structure format. This example creates a 10-by-10 matrix (2-D signal) by using the `magic` function, and then creates a 3-D matrix by adding a time vector.

- 1 In the MATLAB Command Window, enter:

```
t1 = 0.2 * [0:49]';
m = magic(10);
M = repmat(m,[1 1 length(t1)]);
data.time=t1;
data.signals.values = M;
data.signals.dimensions=[10 10];
```

The time vector must be a column vector. The `signals.values` field is a 3-D matrix where the third dimension corresponds to time. The `signals.dimensions` field is a two-element vector. The first element is the number of rows and the second element is the number of columns in the `signals.values` field.

- 2 In the From Workspace block parameters dialog box, in the **Data** field, enter the name of the structure.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
------------	---

Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	No

# Function-Call Feedback Latch

Break feedback loop involving data signals between function-call blocks

## Library

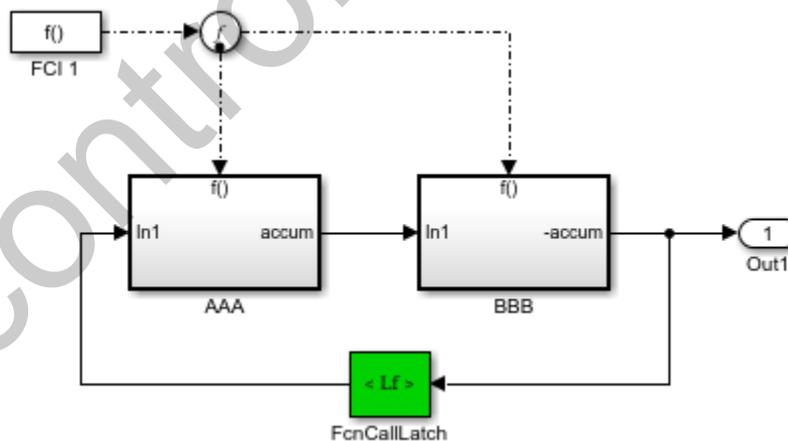

Ports & Subsystems

## Description

Use the Function-Call Feedback Latch block to break a feedback loop of data signals between one or more function-call blocks. Specifically, break a loop formed in one of the following ways.

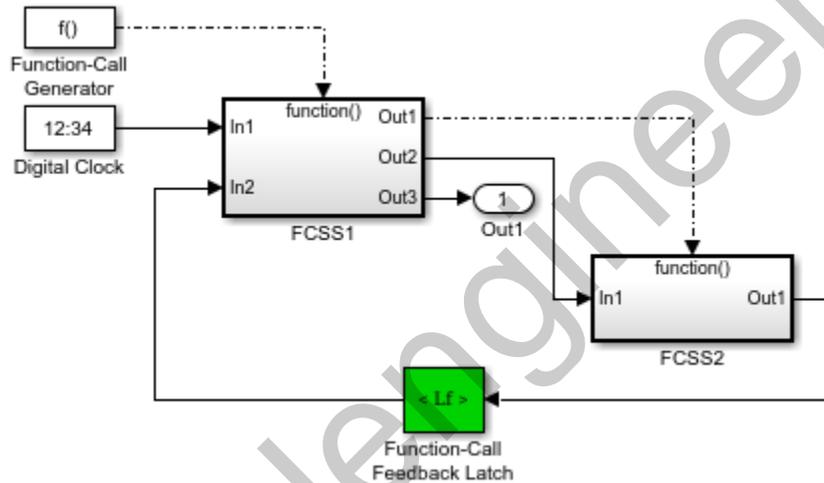

- **When function-call blocks connect to branches of the same function-call signal**

Place the Function-Call Feedback Latch block on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.

- **When the loop involves parent and child function-call blocks, where the child initiator is inside the parent**

Place the Function-Call Feedback Latch block on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent (FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

Using the latch block is equivalent to selecting the **Latch input for function-call feedback signals** check box on the Inport block in the destination function-call subsystem. However, an advantage of the latch block over the dialog parameter is that one can design the destination function-call subsystem (or model) in a modular fashion and then use it either in or out of the context of loops.

The Function-Call Feedback Latch block is better suited than the Unit Delay or Memory blocks in breaking function-call feedback loops for the following reasons:

- The latch block delays the feedback signal for exactly one execution of the source function-call block. This behavior is different from the Unit Delay or Memory blocks for cases where the function-call subsystem blocks may execute multiple times in a given simulation step.
- Unlike the Unit Delay or Memory blocks, the latch block may be used to break loops involving asynchronous function-call subsystems.

- The latch block can result in better performance, in terms of memory optimization, for generated code.

## Data Type Support

The Function-Call Feedback Latch block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

In addition, the latch block accepts bus signals provided that they do not contain any variable-sized signals.

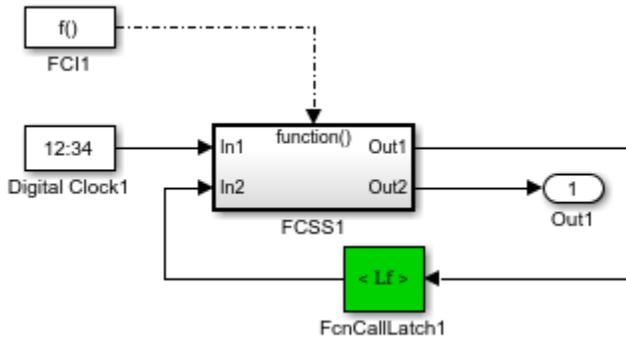

This block does not accept:

- Function-call signals
- Action signals
- Variable-sized signals

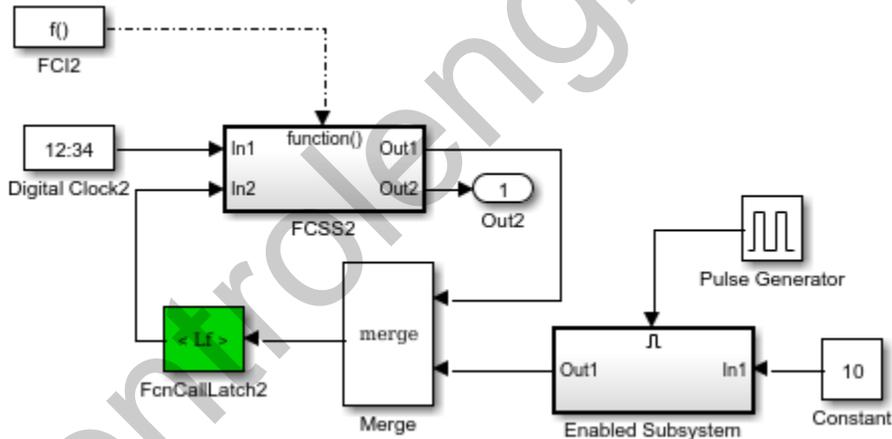

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples

In the following model, a single function-call subsystem output serves as its own input.

A more complex case occurs when a merged signal serves as the input to a function-call subsystem. Latching is necessary if one of the signals entering the Merge block forms a feedback loop with the function-call subsystem. In this example, one of the output signals from FCSS2 combines with the output of an Enabled Subsystem block and then feeds back into an input of FCSS2.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block

Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Function-Call Generator

Execute function-call subsystem specified number of times at specified rate

### Library

Ports & Subsystems

### Description

The Function-Call Generator block executes a function-call subsystem (for example, a Stateflow chart acting as a function-call subsystem) at the rate that you specify with the **Sample time** parameter. To iteratively execute each function-call block connected to this block multiple times at each time step, use the 'Number of Iterations' parameter.

To execute multiple function-call subsystems or models in a prescribed order, use the Function-Call Generator block in conjunction with a Function-Call Split block. For an example, see the Function-Call Split block documentation.

### Data Type Support

The Function-Call Generator block outputs a signal of type `fcn_call`.

### Parameters

#### Sample time

Specify the time interval between samples. See “Specify Sample Time” in the online documentation for more information.

#### Number of iterations

Number of times to execute the block per time step. The value of this parameter can be a vector where each element of the vector specifies a number of times to execute a function-call subsystem. The total number of times that a function-call subsystem executes per time step equals the sum of the values of the elements of the generator signal entering its control port.

Suppose that you specify the number of iterations to be [2 2] and connect the output of this block to the control port of a function-call subsystem. In this case, the function-call subsystem executes four times at each time step.

## Characteristics

Data Types	Not applicable
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Function-Call Split

Provide junction for splitting function-call signal

### Library

Ports & Subsystems

### Description

The Function-Call Split block allows a function-call signal to branch and connect to several function-call subsystems and models.

A Function-Call Split outputs multiple function-call outputs to create multiple branches for a function-call signal. In some cases, when you use this block, you do not need the initiator block to create multiple function-call signals to invoke a set of function-call subsystems or models.

Function-call subsystems or models connected to the output port of the Function-Call Split block that are marked with a dot execute before the subsystems or models connected to other output ports. If any data dependencies between these subsystems (or between models) do not support the specified execution order, the block returns an error. To eliminate this error, consider turning on **Latch input for feedback signals of function-call subsystem outputs** on one or more Inport blocks of the function-call subsystems (or models) involved in a data-dependency loop. Turning on this option delays the corresponding input signal, thereby eliminating the data-dependency loop.

For a model to contain Function-Call Split blocks, you must set the following diagnostic to error: **Model Configuration Parameters > Diagnostics > Connectivity > Invalid function-call connection.**

If you turn on the model option **Format > Block Displays > Sorted Order**, then the execution order of function-call subsystems connected to branches of a given function-call signal appears on the blocks. Each subsystem has an execution order of the form  $S:B\# \{C\}$ . Here, # is a number that ranges from 0 to one less than the total number of subsystems (or models) connected to branches of a given signal. The subsystems execute in ascending order based on this number.

The Function-Call Split block supports signal label propagation.

## Limitations

The Function-Call Split block has these limitations.

- All function-call subsystems and models connected to a given function-call signal must reside within the same nonvirtual layer of the model hierarchy.
- You cannot connect branched function-call subsystems (or models) and their children directly back to the initiator.
- Function-call subsystems and models connected to branches of a function-call signal cannot have multiple (muxed) initiators.
- A Function-Call Split block cannot have its input from a signal with multiple function-call elements.

## Data Type Support

The Function-Call Split block accepts periodic and asynchronous function-call signals only.

## Parameters

### Icon shape

Choose the shape of the icon. Set the icon shape to **round** for a circular block icon, or to **distinctive**.

### Number of output ports

Select the number of output function-call signals.

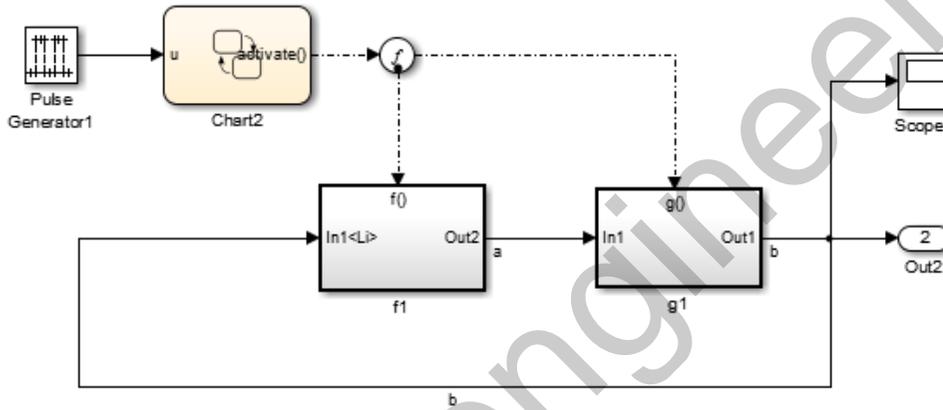

### Output port layout

Choose the layout of the output ports.

## Examples

The following model shows how to apply the **Latch input for feedback signals of function-call subsystem outputs** parameter to work around a data-dependency error

caused by using a Function-Call Split block. By turning this parameter on in the f1 subsystem Inport block, the Function-Call Split block ignores the data dependency of signal b. The block breaks the loop of data dependencies between subsystems f1 and g1. The model achieves the behavior of consistently calling f1 to execute before g1. For a given execution step, subsystem f1 uses the g1 output computed at the previous execution step.

## Characteristics

Data Types	Double
Sample Time	Inherited from the block driving the function-call split
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

## See Also

Function-Call Subsystem | Function-Call Generator

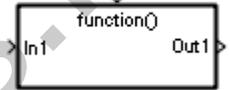

Introduced in R2010a

controlengineers.ir

# Function-Call Subsystem

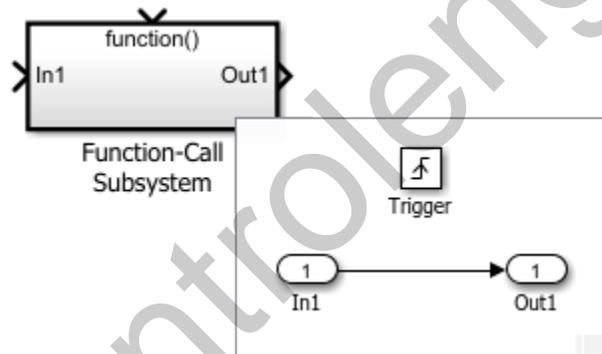

Subsystem whose execution is triggered by external function call input

**Library:** Ports & Subsystems

## Description

The Function-Call Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a function call event.

Use Function-Call Subsystem blocks to:

- Schedule the execution order of model components.
- Control the rate of model component execution.

## Ports

### Input

#### **In** — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### **Function Call** — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

### Output

#### **Out** — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

# Function Caller

Call Simulink or exported Stateflow function

**Library:** User-Defined Functions

## Description

A Function Caller block calls and executes a function defined with a Simulink Function block or an exported Stateflow function. Using Function Caller blocks, you can call a function from anywhere in a model or chart hierarchy.

## Ports

### Input

**Input argument — Input signal for an input argument**

scalar | vector | matrix

Input signal for an input argument that is sent to the function.

The function prototype determines the number and name of input ports that appear on the Function Caller block. Connect signal lines to the input ports to send data to a function through the function input arguments.

For example,  $y = \text{myfunction}(u)$  creates one input port ( $u$ ) on the Function Caller block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

### Output

**Output argument — Output signal for an output argument**

scalar | vector | matrix

Output signal for an output argument that the function returns.

The function prototype determines the number and name of output ports that appear on the Function Caller block. Connect signal lines to the output ports to receive data from a function through the function output arguments.

For example, `y = myfunction(u)` creates one output port (`y`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point` | `enumerated` | `bus`

## Parameters

### Function prototype — Specify function interface

`y=f(u)` (default) | `<function prototype>`

Specify the function interface between a Function Caller block and a Simulink function. A Simulink function can be a Simulink Function block, an exported Stateflow graphical function, or an exported Stateflow MATLAB function. For a call to a Simulink Function block:

- Function call argument names must match the function arguments.
- Function names, input arguments, and output arguments must be valid MATLAB identifiers.

## Programmatic Use

**Block Parameter:** `FunctionPrototype`

**Type:** character vector

**Values:** `'<function prototype>'`

### Input argument specifications — Specify input argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each input argument. For examples, see “Argument Specification for Simulink Functions”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Inport block.

## Programmatic Use

**Block Parameter:** 'InputArgumentSpecifications'

**Type:** character vector

**Values:** '<MATLAB expression>'

**Output argument specifications – Specify output argument data type, dimensions, and complexity**

<Enter example> (default) | <MATLAB Expression>

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each output argument. For examples, see “Argument Specification for Simulink Functions”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Outport Block.

## Programmatic Use

**Block Parameter:** 'OutputArgumentSpecifications'

**Type:** character vector

**Values:** '<MATLAB expression>'

**Sample time – Time interval between function calls**

-1 (default) | <sample time>

By default, the block inherits its sample time based on the context of the block in the model.

To set a different sample time, enter a value using a sample time format from the table in “Specify Sample Time”.

If the Function Caller block has any inputs, it is a nonsource block, and you must set the **Sample time** to -1.

## Programmatic Use

**Block Parameter:** SampleTime

**Type:** character vector  
**Values:** '-1', '<sample time>'  
**Default:** '-1'

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Gain

Multiply input by constant

## Library

Math Operations

## Description

The Gain block multiplies the input by a constant value (gain). The input and the gain can each be a scalar, vector, or matrix.

You specify the value of the gain in the **Gain** parameter. The **Multiplication** parameter lets you specify element-wise or matrix multiplication. For matrix multiplication, this parameter also lets you indicate the order of the multiplicands.

The gain is converted from doubles to the data specified in the block mask offline using round-to-nearest and saturation. The input and gain are then multiplied, and the result is converted to the output data type using the specified rounding and overflow modes.

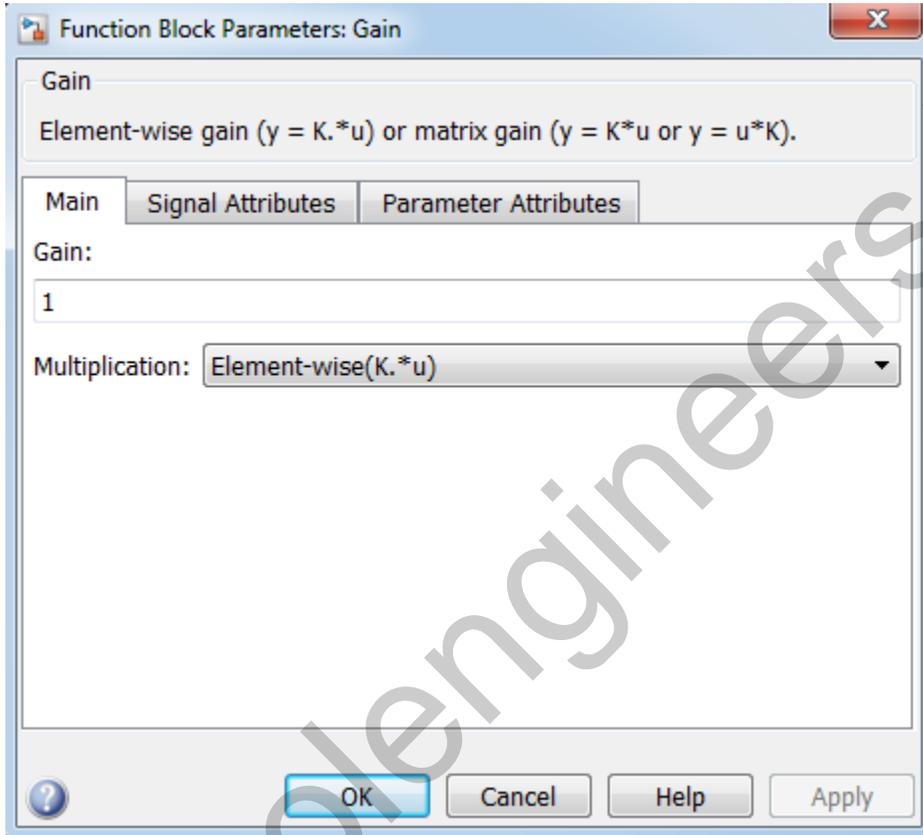

## Data Type Support

The Gain block accepts a real or complex scalar, vector, or matrix of any numeric data type that Simulink supports. The Gain block supports fixed-point data types. If the input of the Gain block is real and the gain is complex, the output is complex.

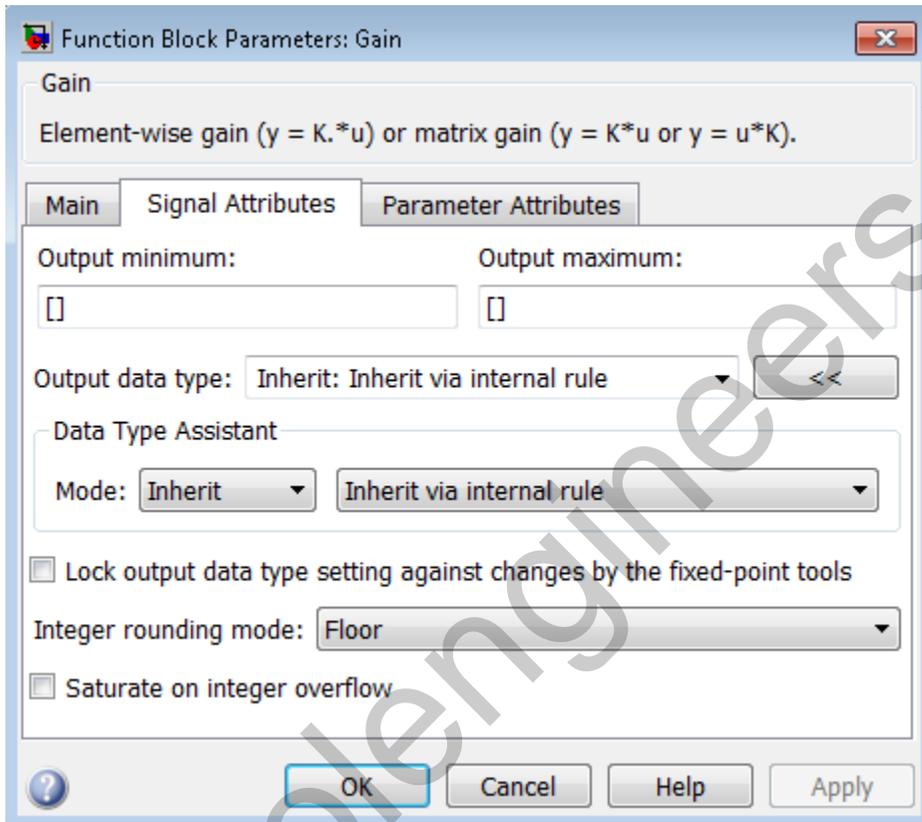

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters and Dialog Box

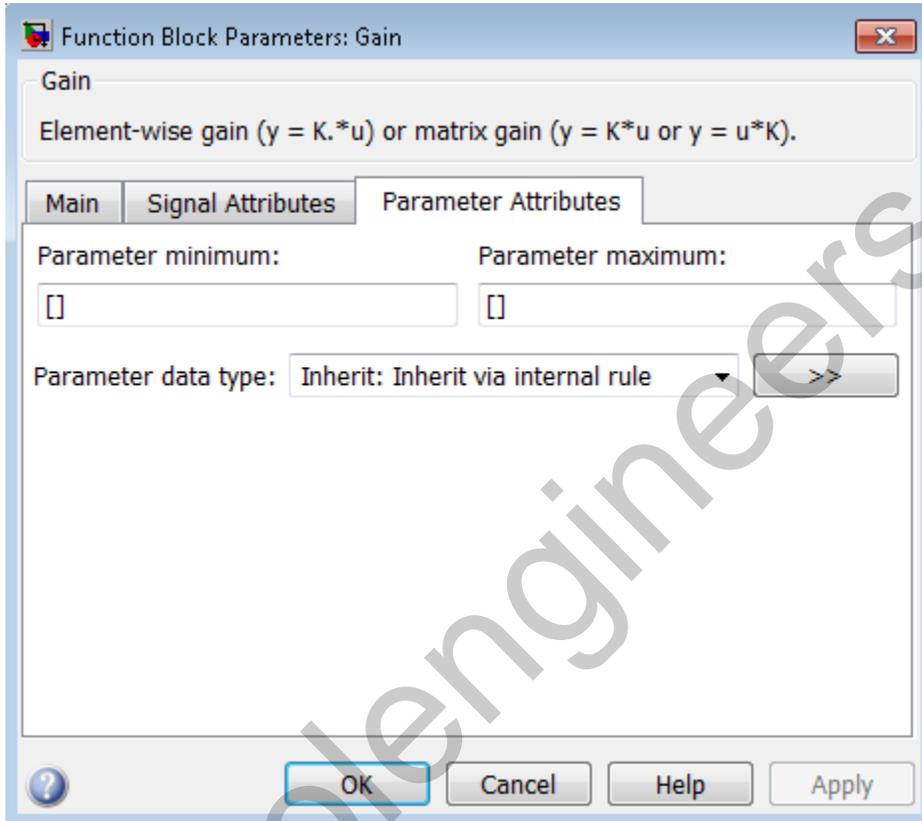

The **Main** pane of the Gain block dialog box appears as follows:

The **Signal Attributes** pane of the Gain block dialog box appears as follows:

The **Parameter Attributes** pane of the Gain block dialog box appears as follows:

## Gain

Specify the value by which to multiply the input.

### Settings

**Default:** 1

**Minimum:** value of **Parameter minimum** parameter

**Maximum:** value of **Parameter maximum** parameter

The gain can be a scalar, vector, or matrix.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Multiplication

Specify the multiplication mode.

### Settings

**Default:** Element-wise ( $K \cdot u$ )

Element-wise ( $K \cdot u$ )

Each element of the input is multiplied by each element of the gain. The block performs expansions, if necessary, so that the input and gain have the same dimensions.

Matrix ( $K \cdot u$ )

The input and gain are matrix multiplied with the input as the second operand.

Matrix ( $u \cdot K$ )

The input and gain are matrix multiplied with the input as the first operand.

Matrix ( $K \cdot u$ ) ( $u$  vector)

The input and gain are matrix multiplied with the input as the second operand. This mode is identical to Matrix ( $K \cdot u$ ), except for how dimensions are determined.

Suppose that  $K$  is an  $m$ -by- $n$  matrix. Matrix ( $K \cdot u$ ) ( $u$  vector) sets the input to a vector of length  $n$  and the output to a vector of length  $m$ . In contrast, Matrix ( $K \cdot u$ ) uses propagation to determine dimensions for the input and output. For an  $m$ -by- $n$  gain matrix, the input can propagate to an  $n$ -by- $q$  matrix, and the output becomes an  $m$ -by- $q$  matrix.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a `Data Type Propagation` block. Examples of how to use this block are available in the Signal Attributes library `Data Type Propagation Examples` block.

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**Inherit:** Same as input

Use data type of input signal.

`double`

Output data type is `double`.

`single`

Output data type is `single`.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Control Signal Data Types” for more information.

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as input

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Parameter minimum

Specify the minimum value of the gain.

### Settings

**Default:** [ ]

The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Parameter maximum

Specify the maximum value of the gain.

### Settings

Default: [ ]

The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Parameter data type

Specify the data type of the **Gain** parameter.

### Settings

**Default:** Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Use an internal rule to inherit the data type.

Inherit: Same as input

Use data type of sole input signal.

Inherit: Inherit from 'Gain'

Use data type of the **Gain** value. For example:

If you set Gain to...	The parameter data type inherits...
2	double
single(2)	single
int8(2)	int8

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is `int32`.

`uint32`

Data type is `uint32`.

`fixdt(1,16)`

Data type is `fixdt(1,16)`.

`fixdt(1,16,0)`

Data type is `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Same as input
- Inherit from 'Gain'

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Examples

The following Simulink examples show how to use the Gain block:

- sldemo\_bounce
- sldemo\_tonegen\_fixpt
- sldemo\_hardstop
- sldemo\_enginewc

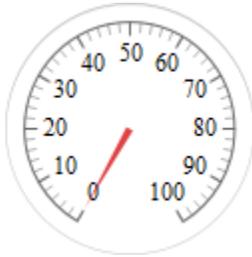

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

## Gauge

Display input value on circular scale

## Library

Dashboard

## Description

The Gauge block displays connected signals during simulation on a circular gauge.

To view data from a signal on the Gauge block, double-click the Gauge block to open the dialog box. Select a signal in the model. The signal appears in the dialog box **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal to the block.

You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

You can also add scale colors that appear on the outside of the Gauge block scale using the **Scale Colors** table.

## Limitations

The Gauge block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to any dashboard gauge, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the gauge and reconnect the signal.

External mode simulation does not support the Gauge block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a signal to connect and display.

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

### Settings

The table has a row for the signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

### Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

### Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

### Scale Colors

Specify ranges of color bands on the outside of the scale. Specify the minimum and maximum color range to display on the gauge.

### Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

#### Top

Show the label at the top of the block.

#### Bottom

Show the label at the bottom of the block.

#### Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

Controlengineers.ir

## Goto

Pass block input to From blocks

## Library

Signal Routing

## Description

The Goto block passes its input to its corresponding From blocks. The input can be a real- or complex-valued signal or vector of any data type. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

A Goto block can pass its input signal to more than one From block, although a From block can receive a signal from only one Goto block. The input to that Goto block is passed to the From blocks associated with it as though the blocks were physically connected. Goto blocks and From blocks are matched by the use of Goto tags.

The **Tag Visibility** parameter determines whether the location of From blocks that access the signal is limited:

- **local**, the default, means that From and Goto blocks using the same tag must be in the same subsystem. A local tag name is enclosed in brackets ([ ]).
- **scoped** means that From and Goto blocks using the same tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, i.e., the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A scoped tag name is enclosed in braces ( { } ).
- **global** means that From and Goto blocks using the same tag can be anywhere in the model except in locations that span nonvirtual subsystem boundaries.

The rule that From-Goto block connections cannot cross nonvirtual subsystem boundaries has the following exception. A Goto block connected to a state port in one conditionally executed subsystem is visible to a From block inside another conditionally executed subsystem.

---

**Note:** A **scoped** Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding **scoped** Goto block in the masked subsystem.

---

Use local tags when the Goto and From blocks using the same tag name reside in the same subsystem. You must use global or scoped tags when the Goto and From blocks using the same tag name reside in different subsystems. When you define a tag as global, all uses of that tag access the same signal. A tag defined as scoped can be used in more than one place in the model.

The Goto block supports signal label propagation.

## Data Type Support

The Goto block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Goto Tag

The Goto block identifier. This parameter identifies the Goto block whose scope is defined in this block.

### Rename All

Rename the Goto tag. The new name propagates to the From and Goto Tag Visibility blocks that are listed in the **Corresponding blocks** box.

### Tag Visibility

The scope of the Goto block tag: **local**, **scoped**, or **global**. The default is **local**.

### Corresponding blocks

List of the From blocks and Goto Tag Visibility blocks connected to this Goto block. Click an entry in the list to display and highlight the corresponding From or Goto Tag Visibility block.

### Icon Display

Specifies the text to display on the block's icon. The options are the block's tag, the name of the signal that the block represents, or both the tag and the signal name.

## Examples

The following models show how to use the Goto block:

- `sldemo_auto_climatecontrol`
- `sldemo_hardstop`

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

From, Goto Tag Visibility

Introduced before R2006a

# Goto Tag Visibility

Define scope of Goto block tag

## Library

Signal Routing

## Description

The Goto Tag Visibility block defines the accessibility of Goto block tags that have scoped visibility. The tag specified as the **Goto tag** parameter is accessible by From blocks in the same subsystem that contains the Goto Tag Visibility block and in subsystems below it in the model hierarchy.

A Goto Tag Visibility block is required for Goto blocks whose **Tag Visibility** parameter value is `scoped`. No Goto Tag Visibility block is needed if the tag visibility is either `local` or `global`. The block shows the tag name enclosed in braces (`{}`).

## Data Type Support

Not applicable.

## Parameters

### Goto tag

The Goto block tag whose visibility is defined by the location of this block.

If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the **Goto** block dialog box.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

# Ground

Ground unconnected input port

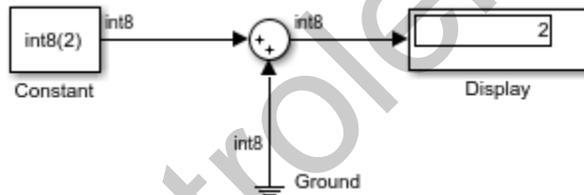

## Library

Sources

## Description

The Ground block connects to blocks whose input ports do not connect to other blocks. If you run a simulation with blocks having unconnected input ports, Simulink issues warnings. Using a Ground block to ground those unconnected blocks can prevent these warnings.

The Ground block outputs a signal of the same data type as the port to which it connects. For example, consider the following model:

In this example, the output of the Constant block determines the data type (int8) of the port to which the Ground block is connected. That port determines the output data type of the Ground block.

The Ground block outputs a signal with zero value. When the output data type cannot represent zero exactly, the Ground block outputs a nonzero value that is the closest possible value to zero. This behavior applies only to fixed-point data types with nonzero bias. The following expressions are examples of fixed-point data types that cannot represent zero:

- `fixdt(0, 8, 1, 1)` — an unsigned 8-bit type with slope of 1 and bias of 1

- `fixdt(1, 8, 6, 3)` — a signed 8-bit type with slope of 6 and bias of 3

If the output is an enumerated data type, the Ground block outputs the default value of the enumeration. This behavior applies whether or not:

- The enumeration can represent zero.
- The default value of the enumeration is zero.

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

## Data Type Support

The Ground block supports all data types that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples

The following Simulink examples show how to use the Ground block:

- `sldemo_doublebounce`

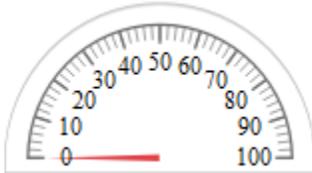

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Constant ( <code>inf</code> )
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

# Half Gauge

Display input value on semicircular scale

## Library

Dashboard

## Description

The Half Gauge block displays connected signals during simulation on a semicircular gauge.

To view data from a signal on the Half Gauge block, double-click the Half Gauge block to open the dialog box. Select a signal in the model canvas. The signal appears in the dialog box **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal to the block.

You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

You can also add scale colors that appear on the outside of the Half Gauge block scale using the **Scale Colors** table.

## Limitations

The Half Gauge block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to any dashboard gauge, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the gauge and reconnect the signal.

External mode simulation does not support the Half Gauge block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a signal to connect and display.

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

### Settings

The table has a row for the signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

## Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

## Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

## Scale Colors

Specify ranges of color bands on the outside of the scale. Specify the minimum and maximum color range to display on the gauge.

## Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

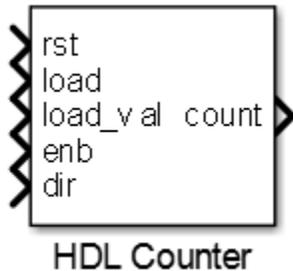

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

Controlengineers.ir

## HDL Counter

Free-running or count-limited hardware counter

### Library

HDL Coder / HDL Operations

### Description

The HDL Counter block models a free-running or count-limited hardware counter that supports signed and unsigned integer and fixed-point data types.

The counter emits its value for the current sample time.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

### Control Ports

By default, the counter does not have input ports. Optionally, you can add control ports that enable, disable, load, reset or set the direction of the counter.

The table shows the priority of the control signals and how the counter value is updated in relation to the control signals.

Local reset, rst	Load trigger, load	Count enable, enb	Count direction, dir	Next Counter Value
1	–	–	–	initial value
0	1	–	–	load_val value
0	0	0	–	current value
0	0	1	1	current value + step value
0	0	1	0	current value - step value

## Count direction

The **Step value** parameter and optional count direction port, **dir**, interact to determine the actual count direction.

dir Signal Value	Step Value Sign	Actual Count Direction
1	+ (positive)	Up
1	- (negative)	Down
0	+ (positive)	Down
0	- (negative)	Up

## Parameters

### Counter type

Counter behavior.

- **Free running** (default): The counter continues to increment or decrement by the **Step value** until reset.
- **Count limited**: The counter increments or decrements by the **Step value** until it is exactly equal to the **Count to value**.

### Initial value

Counter value after reset. The default is 0.

### Step value

Value added to counter at each sample time. The default is 1.

### Count to value

When the count is exactly equal to **Count to value**, the count restarts at the **Initial value**. This option is available when **Counter type** is set to **Count limited**. The default is 100.

### Count from

Specifies the parameter that sets the start value after rollover. When set to **Specify**, the **Count from value** parameter is the start value after rollover. The default is **Initial value**.

### Count from value

Counter value after rollover when **Count from** is set to **Specify**. The default is 0.

### Local reset port

When selected, creates a local reset port, **rst**.

### Load ports

When selected, creates a load data port, **load\_val**, and load trigger port, **load**.

### Count enable port

When selected, creates a count enable port, **enb**.

### Count direction port

When selected, creates a count direction port, **dir**.

### Counter output data is

Output data type signedness. The default is **Unsigned**.

### Word length

Bit width, including sign bit, for an integer counter; word length for a fixed-point data type counter. The minimum value if Output data type is **Unsigned** is 1, 2 if **Signed**. The maximum value is 125. The default is 8.

### Fraction length

Fixed-point data type fraction length. The default is 0.

### Sample time

Sample time. The default is 1.

This parameter is not available, and the block inherits its sample time from the input ports when any of these parameters is selected:

- **Local reset port**

- **Load ports**
- **Count enable port**
- **Count direction port**

## Ports

The block has the following ports:

**rst**

Resets the counter value. Active-high.

This port is available when you select **Local reset port**.

Data type: Boolean

**load**

Sets the counter to the load value, `load_val`. Active-high.

This port is available when you select **Load ports**.

Data type: Boolean

**load\_val**

Data value to load.

This port is available when you select **Load ports**.

Data type: Same as `count`.

**enb**

Enables counter operation. Active-high.

This port is available when you select **Count enable port**.

Data type: Boolean

**dir**

Count direction. This port interacts with **Step value** to determine count direction.

- **1: Step value** is added to the current counter value to compute the next value.

- **0: Step value** is subtracted from the current counter value to compute the next value.

This port is available when you select **Count direction port**.

Data type: Boolean

count

Counter value.

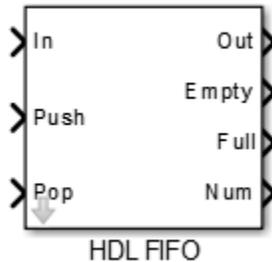

Data type: Determined automatically based on **Counter output data is**, **Word length**, and **Fraction length**.

**Introduced in R2014a**

Controlengineers.ir

## HDL FIFO

Stores sequence of input samples in first in, first out (FIFO) register

### Library

HDL Coder / HDL Operations

### Description

The HDL FIFO block stores a sequence of input samples in a first in, first out (FIFO) register.

### HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

## Parameters

### Register size

Specify the number of entries that the FIFO register can hold. The minimum is 4. The default is 10.

### The ratio of output sample time to input sample time

Inputs (In, Push) and outputs (Out, Pop) can run at different sample times. Enter the ratio of output sample time to input sample time. Use a positive integer or  $1/N$ , where  $N$  is a positive integer. The default is 1.

For example:

- If you enter 2, the output sample time is twice the input sample time, meaning the outputs run slower.
- If you enter  $1/2$ , the output sample time is half the input sample time, meaning the outputs run faster.

The Full, Empty, and Num signals run at the faster rate.

### Push onto full register

Response (Ignore, Error, or Warning) to a trigger received at the Push port when the register is full. The default is Warning.

### Pop empty register

Response (Ignore, Error, or Warning) to a trigger received at the Pop port when the register is empty. The default is Warning.

### Show empty register indicator port (Empty)

Enable the Empty output port, which is high (1) when the FIFO register is empty and low (0) otherwise.

### Show full register indicator port (Full)

Enable the Full output port, which is high (1) when the FIFO register is full and low (0) otherwise.

### Show number of register entries port (Num)

Enable the Num output port, which tracks the number of entries currently in the queue.

## Ports

The block has the following ports:

**In**

Data input signal.

**Push**

Control signal. When this port receives a value of 1, the block pushes the input at the In port onto the end of the FIFO register.

**Pop**

Control signal. When this port receives a value of 1, the block pops the first element off the FIFO register and holds the Out port at that value.

**Out**

Data output signal.

**Empty**

The block asserts this signal when the FIFO register is empty. This port is optional.

**Full**

The block asserts this signal when the FIFO register is full. This port is optional.

**Num**

Current number of data values in the FIFO register. This port is optional.

If two or more of the control input ports are triggered in the same time step, the operations execute in the following order:

- 1 Pop
- 2 Push

## HDL Reciprocal

Calculate reciprocal with Newton-Raphson approximation method

HDL Reciprocal

## Library

HDL Coder / HDL Operations

## Description

The HDL Reciprocal block uses the Newton-Raphson iterative method to compute the reciprocal of the block input. The Newton-Raphson method uses linear approximation to successively find better approximations to the roots of a real-valued function.

The reciprocal of a real number  $a$  is defined as a zero of the function:

$$f(x) = \frac{1}{x} - a$$

HDL Coder chooses an initial estimate in the range  $0 < x_0 < \frac{2}{a}$  as this is the domain of convergence for the function.

To successively compute the roots of the function, specify the **Number of iterations** parameter in the Block Parameters dialog box. The process is repeated as:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i + (x_i - ax_i^2) = x_i \cdot (2 - ax_i)$$

$f'(x)$  is the derivative of the function  $f(x)$ .

Following table shows comparison of simulation behavior of HDL Reciprocal with Math Reciprocal block:

Math Reciprocal	HDL Reciprocal
Computes the reciprocal as $1/N$ by using the HDL divide operator (/) to implement the division.	Uses the Newton-Raphson iterative method. The block computes an approximate value of reciprocal of the block input and can yield different simulation results compared to the Math Reciprocal block.  To match the simulation results with the Math Reciprocal block, increase the number of iterations for the HDL Reciprocal block.

## Parameters

### Number of iterations

Number of Newton-Raphson iterations. The default is 3.

## Ports

The block has the following ports:

### Input

- Supported data types: Fixed-point, integer (signed or unsigned), double, single
- Minimum bit width: 2
- Maximum bit width: 128

### Output

Input data type	Output data type
double	double
single	single
built-in integer	built-in integer
built-in fixed-point	built-in fixed-point

Input data type	Output data type
<code>fi (value, 0, word_length, fraction_length)</code>	<code>fi (value, 0, word_length, word_length-fraction_length-1)</code>
<code>fi (value, 1, word_length, fraction_length)</code>	<code>fi (value, 1, word_length, word_length-fraction_length-2)</code>

## Hit Crossing

Detect crossing point

### Library

Discontinuities

### Description

The Hit Crossing block detects when the input reaches the **Hit crossing offset** parameter value in the direction specified by the **Hit crossing direction** property.

The block accepts one input of type **double**. If you select the **Show output port** check box, the block output indicates when the crossing occurs. If the input signal is exactly the value of the offset value after the hit crossing is detected, the block continues to output a value of 1. If the input signals at two adjacent points bracket the offset value (but neither value is exactly equal to the offset), the block outputs a value of 1 at the second time step. If the **Show output port** check box is *not* selected, the block ensures that the simulation finds the crossing point but does not generate output. If the input signal is constant and equal to the offset value, the block outputs 1 only if the **Hit crossing direction** property is set to **either**.

When the block's **Hit crossing direction** property is set to **either**, the block serves as an "Almost Equal" block, useful in working around limitations in finite mathematics and computer precision. Used for these reasons, this block might be more convenient than adding logic to your model to detect this condition.

When the block's **Hit crossing direction** property is set to **either** and the model uses a fixed-step solver, the block has the following behavior. If the output signal is 1, the block sets the output signal to 0 at the next time step, unless the input signal equals the offset value.

## Data Type Support

The Hit Crossing block outputs a signal of type **Boolean** if Boolean logic signals are enabled (see “Implement logic signals as Boolean data (vs. double)”). Otherwise, the block outputs a signal of type **double**.

## Parameters

### Hit crossing offset

The value whose crossing is to be detected.

### Hit crossing direction

The direction from which the input signal approaches the hit crossing offset for a crossing to be detected.

### Show output port

If selected, draw an output port.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

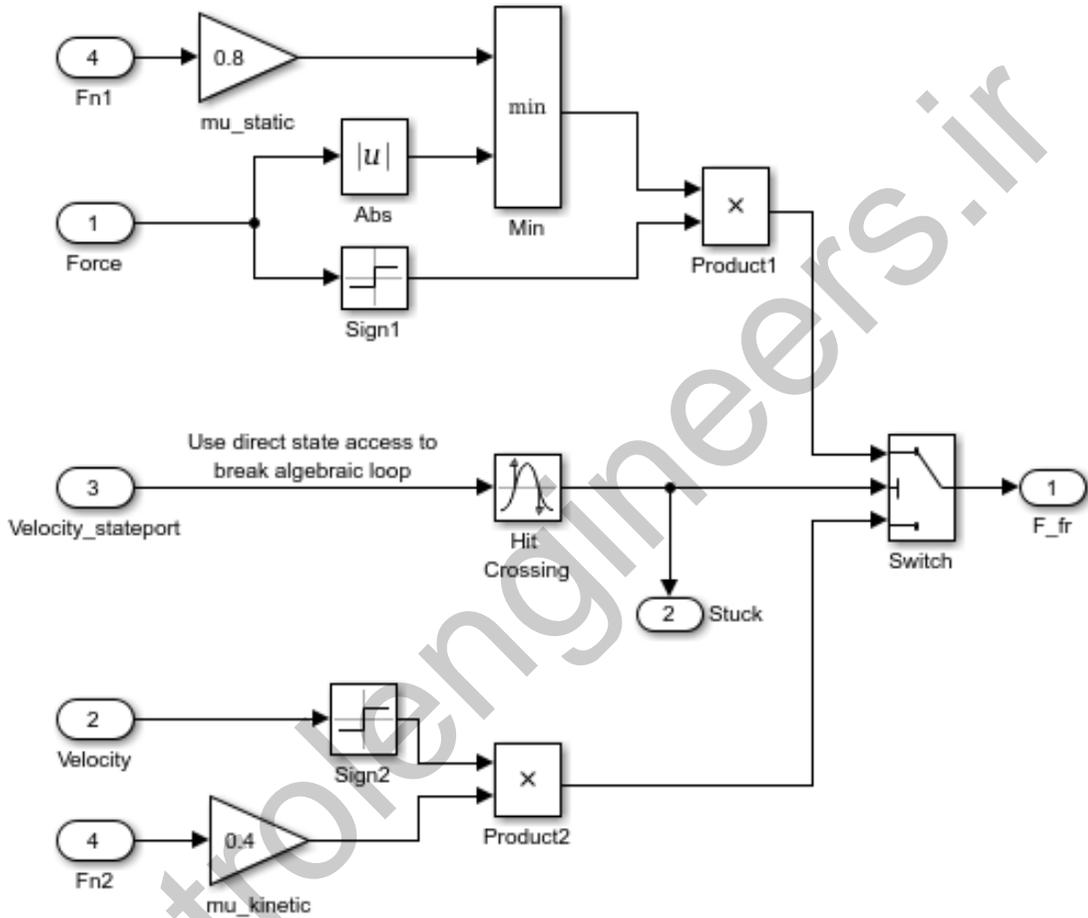

---

## Examples

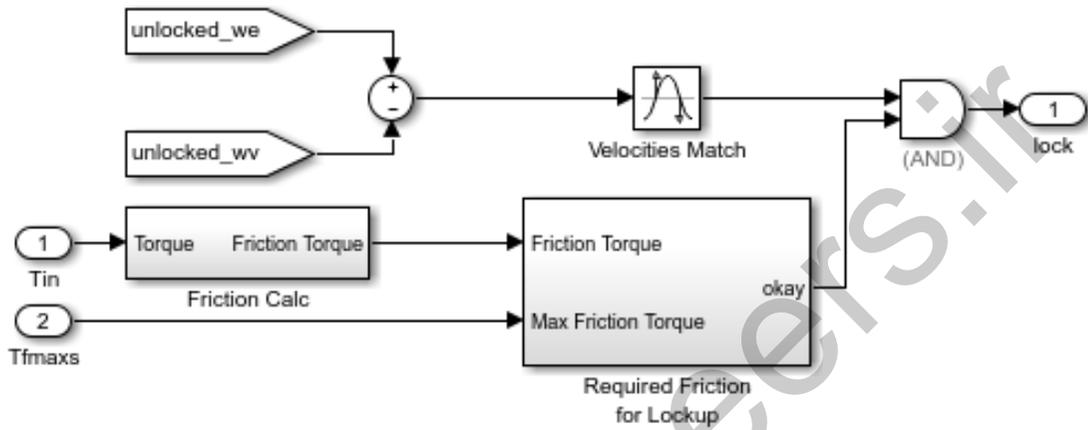

The `sldemo_hardstop` and `sldemo_clutch` models show how you can use the Hit Crossing block.

In the `sldemo_hardstop` model, the Hit Crossing block is in the Friction Model subsystem.

1 Blocks – Alphabetical List

In the `sldemo_clutch` model, the Hit Crossing block is in the Friction Mode Logic/ Lockup Detection subsystem.

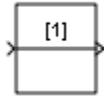

## Characteristics

Data Types	Double
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

## IC

Set initial value of signal

## Library

Signal Attributes

## Description

The IC block sets the initial condition of the signal at its input port, for example, the value of the signal at the simulation start time ( $t_{start}$ ). The block does this by outputting the specified initial condition when you start the simulation, regardless of the actual value of the input signal. Thereafter, the block outputs the actual value of the input signal.

---

**Note:** If an IC block has a nonzero sample time offset ( $t_{offset}$ ), the IC block outputs its initial value at time  $t$ ,

$$t = n * t_{period} + t_{offset}$$

where  $n$  is the smallest integer such that  $t \geq t_{start}$ .

That is, the IC block outputs its initial value the first time blocks with sample time  $[t_{period}, t_{offset}]$  execute, which can be after  $t_{start}$ .

---

The IC block is useful for providing an initial guess for the algebraic state variables in a loop. For more information, see “Algebraic Loops”.

## Data Type Support

The IC block accepts and outputs signals of any Simulink built-in and fixed-point data type. The **Initial value** parameter accepts any built-in data type that Simulink supports. For more information, see “Data Types Supported by Simulink”.

## Parameters

### Initial value

Specify the initial value for the input signal.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

The following examples show how to use the IC block:

- sldemo\_bounce
- sldemo\_hardstop
- sldemo\_enginewc

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No

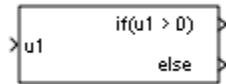

Zero-Crossing Detection	No
Code Generation	Yes

## If

Model if - else control flow

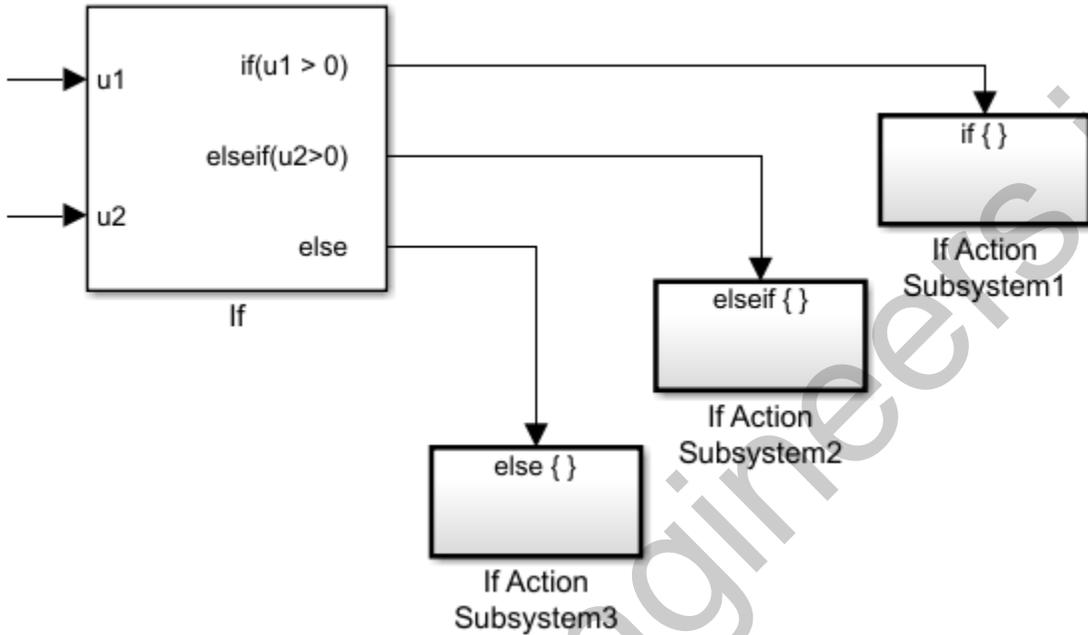

## Library

Ports & Subsystems

## Description

The If block, along with the If Action Subsystem block containing an Action Port, implements if-else logic.

The following shows a completed if-else control flow statement.

In this example, the inputs to the If block determine the values of conditions represented as output ports. Each output port is attached to an If Action Subsystem block. The conditions are evaluated top down starting with the `if` condition. If a condition is true, its If Action Subsystem is executed and the If block does not evaluate any remaining conditions.

The preceding if-else control flow statement can be represented by the following pseudocode.

```

if (u1 > 0) {
    If Action Subsystem1;
}
else if (u2 > 0){
    If Action Subsystem2;
}
else {
    If Action Subsystem3;
}
    
```

You construct a Simulink if-else control flow statement like the preceding example as follows:

- 1 Place an If block in the current system.
- 2 Open the dialog of the If block and enter as follows:
  - Enter the **Number of inputs** field with the required number of inputs necessary to define conditions for the **if-else** control flow statement.

Elements of vector inputs can be accessed for conditions using (row, column) arguments. For example, you can specify the fifth element of the vector u2 in the condition  $u2(5) > 0$  in an **If expression** or **Elseif expressions** field.

- Enter the expression for the if condition of the **if-else** control flow statement in the **If expression** field.

This creates an if output port for the If block with a label of the form **if (condition)**. This is the only required If Action signal output for an If block.

- Enter expressions for any elseif conditions of the **if-else** control flow statement in the **Elseif expressions** field.

Use a comma to separate one condition from another. Entering these conditions creates an output port for the If block for each condition, with a label of the form **elseif (condition)**. elseif ports are optional and not required for operation of the If block.

- Check the **Show else condition** check box to create an else output port.

The else port is optional and not required for the operation of the If block.

- 3 Add If Action Subsystem blocks to connect to each of the if, else, and elseif ports.

These consist of a subsystem with an Action Port block. When you place an Action Port block inside each subsystem, an input port named Action is added to the subsystem.

- 4 Connect each if, else, and elseif port of the If block to the action port of an If Action Subsystem block.

When you make the connection, the icon for the If Action block is renamed to the type of the condition that it attaches to.

---

**Note** During simulation of an **if-else** control flow statement, the Action signal lines from the If block to the If Action subsystems turn from solid to dashed.

---

- 5 In each **If Action Subsystem**, enter the Simulink blocks appropriate to the body to be executed for the condition it handles.

## Limitations

The If block has the following limitations:

- You cannot tune an if or elseif expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. The If block does not support tunable parameters. To implement tunable if-else expressions, tune the expression outside the If block. For example, use the Relational operator block to evaluate the expression outside or add the tunable parameter as an input to the If block.
- The If block does not support custom storage classes. See “Custom Storage Classes” (Embedded Coder) in the Embedded Coder documentation.
- The **If expression** and **Elseif expressions** cannot accept certain operators, such as +, -, \*, and /. See If Expression and Elseif Expressions in “Parameters” on page 1-806

## Data Type Support

Inputs  $u_1, u_2, \dots, u_n$  can be scalars or vectors of any built-in Simulink data type and must all be of the same data type. The inputs cannot be of any user-defined type, such as an enumerated type. Outputs from the **if**, **else**, and **elseif** ports are action signals to If Action Subsystem blocks that you create by using Action Port blocks and subsystems.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of inputs

Specify the number of inputs to the If block. These appear as data input ports labeled with a 'u' character followed by a number,  $1, 2, \dots, n$ , where  $n$  equals the number of inputs that you specify.

### If expression

Specify the condition for the **if** output port. This condition appears on the **If** block adjacent to the **if** output port. The **If expression** can include only the operators **<**, **<=**, **==**, **~=**, **>**, **>=**, **&**, **|**, **~**, **()**, **unary-minus**, and cannot include operators such as **+**, **-**, **\***, **/**, and **^**. The **If Action Subsystem** attached to the **if** port executes if its condition is true. The expression must not contain data type expressions, for example, **int8(6)**, and must not reference workspace variables whose data type is other than **double** or **single**.

---

**Note:** There are limitations to the tunability of the **If expression**. See “Limitations” on page 1-806 for more information.

---

### Elseif expressions

Specify a character vector list of **elseif** conditions delimited by commas. These conditions appear below the **if** port and above the **else** port when you select the **Show else condition** check box. **Elseif expressions** can include only the operators **<**, **<=**, **==**, **~=**, **>**, **>=**, **&**, **|**, **~**, **()**, **unary-minus**, and cannot include operators such as **+**, **-**, **\***, **/**, and **^**. The **If Action Subsystem** attached to an **elseif** port executes if its condition is true and all of the **if** and **elseif** conditions are false. The expression must not contain data type expressions, for example, **int8(6)**, and must not reference workspace variables whose data type is other than **double** or **single**.

---

**Note:** There are limitations to the tunability of **Elseif expressions**. See “Limitations” on page 1-806 for more information.

---

### Show else condition

If you select this check box, an **else** port is created. The **If Action** subsystem attached to the **else** port executes if the **if** port and all the **elseif** ports are false.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

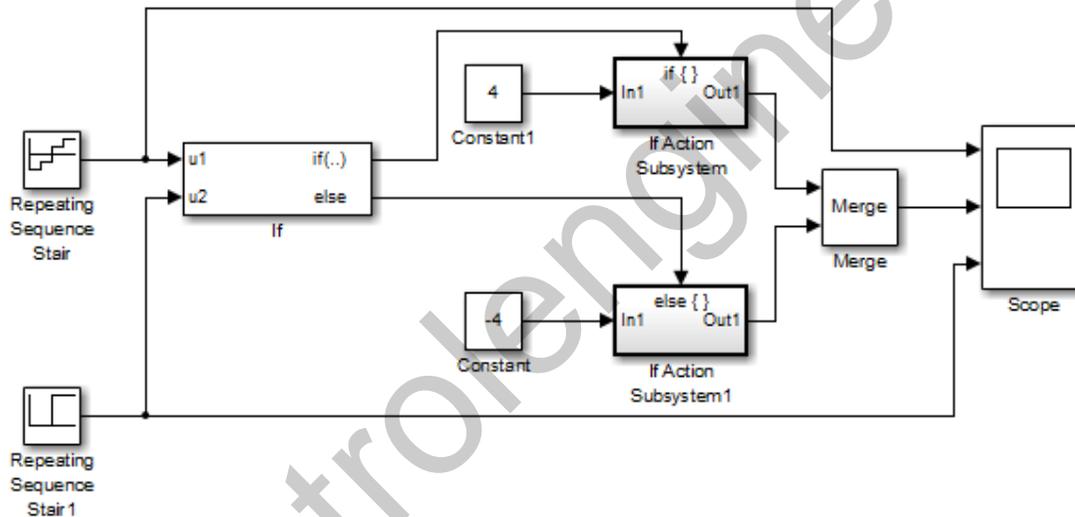

### Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

## Examples

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation.

For example, consider the following floating-point model:

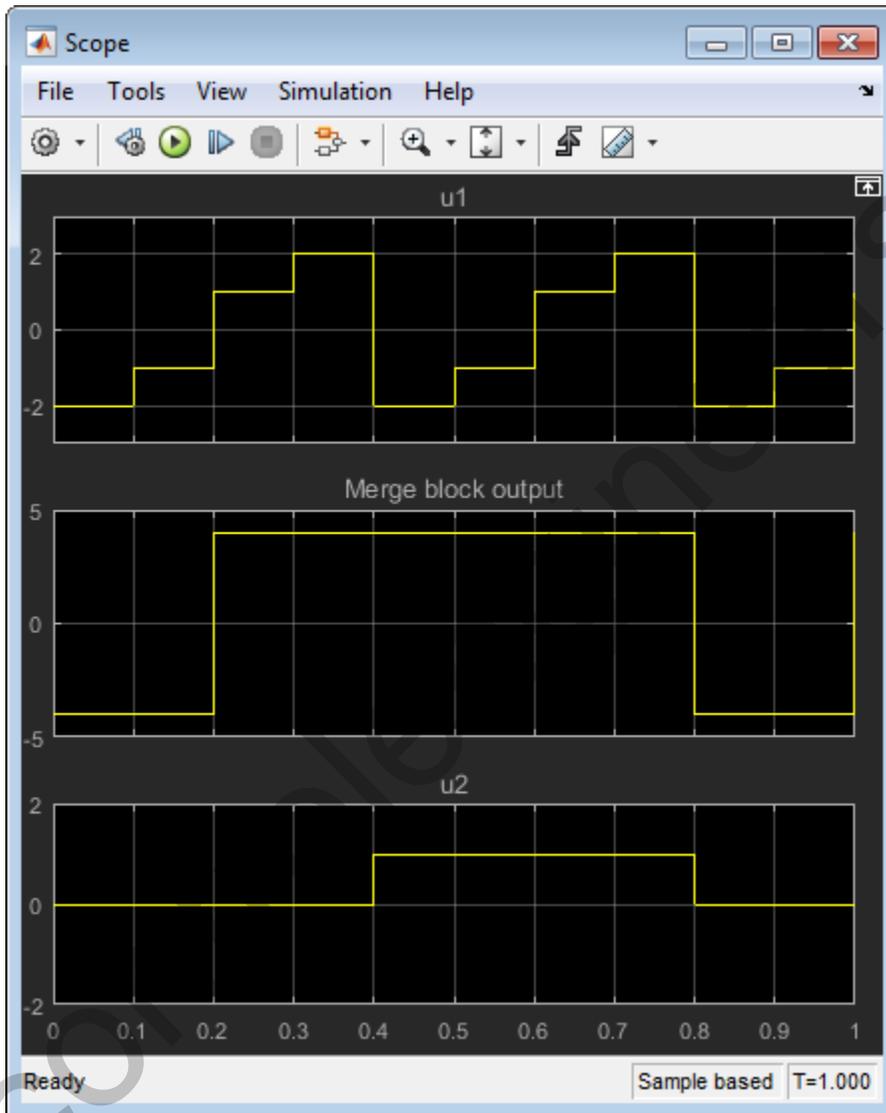

In this model, the If Action subsystems use their default configurations. The block and simulation parameters for the model are set to their default values except as follows:

Block or Dialog Box	Parameter	Setting
Configuration Parameters — Solver pane	Start time	0.0
	Stop time	1.0
	Type	Fixed-step

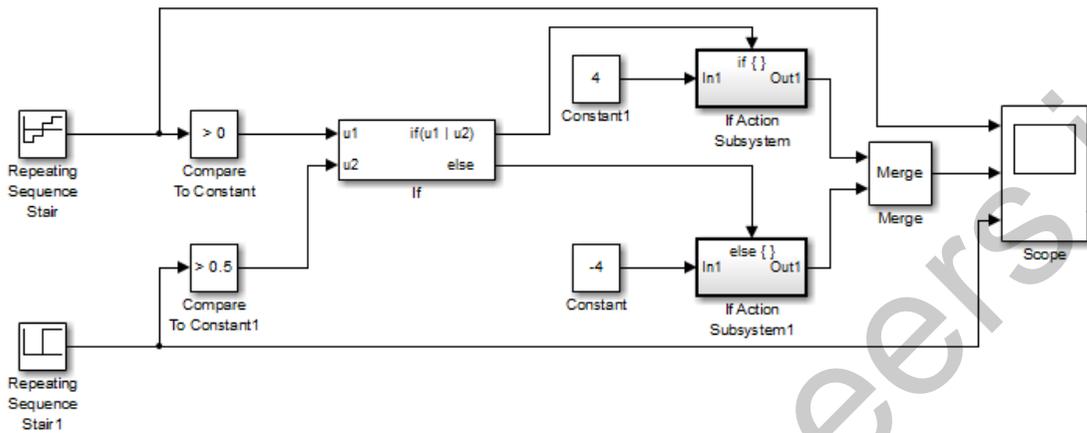

Block or Dialog Box	Parameter	Setting
	<b>Solver</b>	discrete (no continuous states)
	<b>Fixed-step size</b>	0.1
Repeating Sequence Stair	<b>Vector of output values</b>	[-2 -1 1 2].'
Repeating Sequence Stair1	<b>Vector of output values</b>	[0 0 0 0 1 1 1 1].'
If	<b>Number of inputs</b>	2
	<b>If expression</b>	(u1 > 0)   (u2 > 0.5)
	<b>Show else condition</b>	selected
Constant	<b>Constant value</b>	-4
Constant1	<b>Constant value</b>	4
Scope	<b>Number of axes</b>	3
	<b>Time range</b>	1

For this model, if input u1 is greater than 0 or input u2 is greater than 0.5, the output is 4. Otherwise, the output is -4. The Scope block shows the output, u1, and u2:

ControlEngineers.ir

You can implement this block diagram as a model with fixed-point data types:

The Repeating Sequence Stair blocks now output fixed-point data types.

The Compare To Constant blocks implement two parts of the **If expression** that is used in the If block in the floating-point version of the model,  $(u1 > 0)$  and  $(u2 > 0.5)$ . The OR operation,  $(u1 | u2)$ , can still be implemented inside the If block. For a fixed-point model, the expression must be partially implemented outside of the If block as it is here.

The block and simulation parameters for the fixed-point model are the same as for the floating-point model with the following exceptions and additions:

Block	Parameter	Setting
Compare To Constant	<b>Operator</b>	>
	<b>Constant value</b>	0
	<b>Output data type mode</b>	Boolean
	<b>Enable zero-crossing detection</b>	off
Compare To Constant1	<b>Operator</b>	>
	<b>Constant value</b>	0.5
	<b>Output data type mode</b>	Boolean
	<b>Enable zero-crossing detection</b>	off
If	<b>Number of inputs</b>	2

Block	Parameter	Setting
	If expression	u1   u2

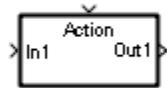

## Characteristics

Data Types	Double   Single   Boolean   Base Integer
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

## If Action Subsystem

Represent subsystem whose execution is triggered by If block

## Library

Ports & Subsystems

## Description

The If Action Subsystem block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by an If block.

---

**Note:** All blocks in an If Action Subsystem must run at the same rate as the driving If block. You can achieve this by setting each block's sample time parameter to be either inherited (-1) or the same value as the If block's sample time.

---

For more information, see “Action Subsystem”, If block and Modeling with Control Flow Blocks in the “Creating a Model” chapter of the Simulink documentation.

## Characteristics

## In Bus Element

Select bus element or entire bus that is connected to subsystem input port

**Library:** Ports & Subsystems

InBus.signal1 

### Description

**Note:** This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Ports & Subsystems library — In Bus Element
- In the Signal Routing library — Bus Element In

Select an element from a bus (or the entire bus) that is connected to the input port of the subsystem. This block integrates into one block the functionality of using an Inport block and a Bus Selector block. The In Bus Element block is of the Inport block type. There are no specifications allowed on an In Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an In Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and OutBusElement blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
- For input, avoid a duplicate Inport blocks and a Bus Selector, Goto, and From block configuration.
- For output, avoid a Goto, From, and Bus Creator block configuration.

The In Bus Element block selects signals from a subsystem input port. Feed the output of the In Bus Element block to another block in the subsystem.

To select a signal from the input port, use one of these approaches:

- In the Block Parameters dialog box, select one or more signals from the list of signals and click **Add block**.
- In the Simulink Editor, edit the element part of the block icon text. If the port is already connected outside the subsystem, you can select from a list of available signals. For example, the default icon text is `InBus.signal1`. To specify an element, edit the `signal1` text.

For bus input signals, either specify the signal that you want to select from the input port or to pass through the whole bus signal, leave the element empty. For a nonbus input signal for a subsystem, leave the element section of the block icon text empty. The block passes through the value of the nonbus signal.

To select multiple signals from an input bus signal, create multiple In Bus Element blocks, one for each selected signal.

- Drag the block from the Library Browser. This creates a new port.
- Use quick insert. This creates a new port.
- Copy the block from an existing block. Either use copy and paste or right-click and drag the block. Then specify whether to use the same port as the original block for new block or to create a new subsystem port.
- In the Block Parameters dialog box list of input signals, select a signal and click .

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

## Ports

The block does not have an input port. Use the Block Parameters dialog box or Property Inspector to specify the subsystem input port from which the block receives its input signal.

## Output

### Port\_1 — Pass selected signal to another block

signal

The output port passes the value of the selected input signal to another block. The signal can have a real or complex value of any data type that Simulink supports.

## Parameters

### Port name — Name of associated subsystem input port

InBus (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and In Bus Element block icons. If you specify a port name, that name cannot already be in use by another In Bus Element block or port. All In Bus Element blocks that access the same subsystem input port reflect the port name that you specify.

## Programmatic Use

**Block Parameter:** PortName

**Type:** text

**Default:** InBus

### Port number — Position in which port appears for subsystem input ports

1 (default) | integer

Specify the order in which the port appears on the subsystem, with 1 being the top port, 2 the second port down, and so on.

- If you specify a number that exceeds the number of subsystem input ports, new ports are added above the port associated with the In Bus Element block.
- If you add an In Bus Element block that creates another subsystem input port, the port number is the next available number.
- If you delete all In Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

## Programmatic Use

**Block Parameter:** Port

**Value:** integer

**Default:** 1

# Increment Real World

Increase real world value of signal by one

**Library:** Simulink / Additional Math & Discrete / Additional  
 Math: Increment — Decrement

## Description

The Increment Real World block increases the real world value of the signal by one.

Overflows always wrap.

## Ports

### Input

**Port\_1 (u) — Input signal**  
 Scalar

The Increment Real World block accepts signals of the data types listed below.

For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

### Output

**Port\_1 (y) — Calculated output signal**  
 Scalar

Output data type always matches input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

## Block Characteristics

<b>Data Types</b>	<code>double</code>   <code>single</code>   <code>base_integer</code>   <code>fixed_point</code>
<b>Sample Time</b>	Inherit
<b>Direct Feedthrough</b>	Yes
<b>Multidimensional Signals</b>	Scalar
<b>Variable-Size Signals</b>	Yes
<b>Zero-Crossing Detection</b>	No

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

## HDL Architecture

This block has a single, default HDL architecture.

## HDL Block Properties

### ConstrainedOutputPipeline

Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0.

See also “ConstrainedOutputPipeline” (HDL Coder).

### InputPipeline

Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0.

See also “InputPipeline” (HDL Coder).

### OutputPipeline

Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0.

See also “OutputPipeline” (HDL Coder).

## Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

## Increment Stored Integer

Increase stored integer value of signal by one

### Library

Additional Math & Discrete / Additional Math: Increment - Decrement

### Description

The Increment Stored Integer block increases the stored integer value of a signal by one.

Floating-point signals also increase by one, and overflows always wrap.

### Data Type Support

The Increment Stored Integer block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point

# Initialize Function

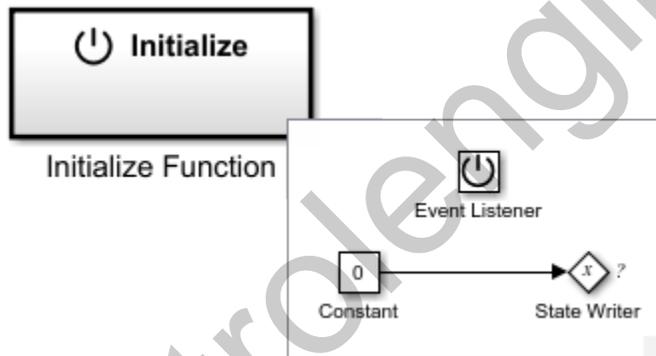

Executes contents on a model initialize event

**Library:** User-Defined Functions

## Description

The Initialize Function block is a pre-configured subsystem block that executes on a model initialize event. By default, the Initialize Function block includes an Event Listener block with **Event** set to **Initialize**, a Constant block with **Constant value** set to 0, and a State Writer block.

Replace the Constant block with blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_initialize` function that is called once at the beginning of model execution.

## Inport

Create input port for subsystem or external input

## Library

Ports & Subsystems, Sources

## Description

Inport blocks are the links from outside a system into the system.

Simulink software assigns Inport block port numbers according to these rules:

- It automatically numbers the Inport blocks within a top-level system or subsystem sequentially, starting with 1.
- If you add an Inport block, the label is the next available number.
- If you delete an Inport block, other port numbers are automatically renumbered to ensure that the Inport blocks are in sequence and that no numbers are omitted.
- If you copy an Inport block into a system, its port number is *not* renumbered unless its current number conflicts with an Inport block already in the system. If the copied Inport block port number is not in sequence, renumber the block. Otherwise, you get an error message when you run the simulation or update the block diagram.

You can specify the dimensions of the input to the Inport block using the **Port dimensions** parameter. Entering a value of -1 lets Simulink determine the port dimension.

The **Sample time** parameter is the rate at which the signal is coming into the system. A value of -1 causes the block to inherit its sample time from the block driving it. You might need to set this parameter for:

- Inport blocks in a top-level system.

- Models with blocks where Simulink cannot determine the sample time, but these blocks drive Inport blocks.

For more information, see “Specify Sample Time”.

## Inport Blocks in a Top-Level System

You can use an Inport block in a top-level system to:

- Supply external inputs from the workspace using one of these approaches. If no external outputs are supplied, then the default output is the ground value.
  - Use the **Configuration Parameters > Data Import/Export > Input** parameter. See “Specify Data for Root-Level Input Ports”.

---

**Tip:** To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Data Using Root Inport Mapper Tool”.

---

- Use the `ut` argument of the `sim` command (see `sim`) to specify the inputs.
- Provide a means for perturbation of the model by the `linmod` and `trim` analysis functions.
  - Use Inport blocks to inject inputs into the system. See “Linearizing Models”.
- To load logged signal data using root Inport blocks, you can use the `createInputDataset` function to create a `Dataset` object that contains elements that correspond to root-level Inport blocks in the model.

## Inport Blocks in a Subsystem

Inport blocks in a subsystem represent inputs to the subsystem. A signal arriving at an input port on a Subsystem block flows out of the associated Inport block in that subsystem. The Inport block associated with an input port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the input port on the Subsystem block. For example, the Inport block whose **Port number** parameter is 1 gets its signal from the block connected to the topmost port on the Subsystem block.

If you renumber the **Port number** of an Inport block, the block becomes connected to a different input port, although the block continues to receive its signal from the same block outside the subsystem.

The Inport block name appears in the Subsystem icon as a port label. To suppress display of the label, select the Inport block and choose **Format > Hide Name**.

Inport blocks inside a subsystem support signal label propagation, but root-level Inport blocks do not.

You can use a subsystem inport to supply fixed-point data in a structure or any other format.

---

**Tip:** For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an In Bus Element block to specify bus element attributes, such as data type or dimensions.

---

## Creating Duplicate Inports

You can create any number of duplicates of an Inport block. The duplicates are graphical representations of the original intended to simplify block diagrams by eliminating unnecessary lines. The duplicate has the same port number, properties, and output as the original. Changing properties of a duplicate changes properties of the original and vice versa.

To create a duplicate of an Inport block:

- 1 In the block diagram, select the block that you want to duplicate.
- 2 In the Model Editor menu bar, select **Edit > Copy**.
- 3 In the block diagram, place your cursor where you want to place the duplicate.
- 4 Select **Edit > Paste Duplicate Inport**.

## Connecting Buses to Root-Level Inports

If you want a root-level Inport of a model to produce a bus signal, you must set the **Data type** parameter to the name of a bus object that defines the bus that the Inport produces. For more information, see “When to Use Bus Objects”.

## Data Type Support

The Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Inport block also accepts a bus object as a data type.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

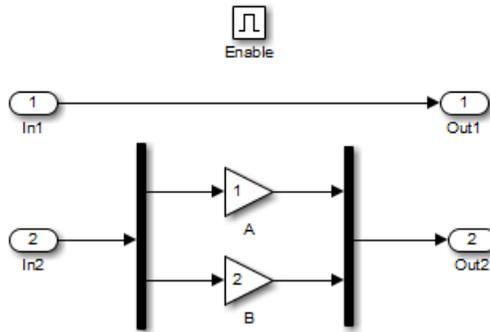

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

---

For more information, see “Data Types Supported by Simulink”.

The numeric and data types of the block output are the same as those of its input. You can specify the signal type and data type of an external input to a root-level Inport block using the **Signal type** and **Data type** parameters.

The elements of a signal array connected to a root-level Inport block must be of the same numeric and data types. Signal elements connected to a subsystem input port can be of differing numeric and data types, except in the following circumstance: If the subsystem contains an Enable, Trigger, or Atomic Subsystem block and the input port, or an element of the input port, connects directly to an output port, the input elements must be of the same type. For example, consider the following enabled subsystem:

In this example, the elements of a signal vector connected to In1 must be of the same type. The elements connected to In2, however, can be of differing types.

## Parameters

Controlengineers.ir

## Port number

Specify the port number of the block.

### Settings

**Default:** 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Icon display

Specify the information to be displayed on the icon of this input port.

### Settings

**Default:** Port number

Signal name

Display the name of the signal connected to this port (or signals if the input is a bus).

Port number

Display port number of this port.

Port number and signal name

Display both the port number and the names of the signals connected to this port.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Latch input by delaying outside signal

Output the value of the input signal at the previous time step.

### Settings

**Default:** Off

On

Output the value of the input signal at the previous time step.

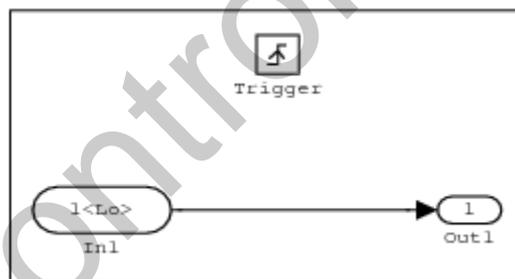

Off

Do not output the value of the input signal at the previous time step.

### Tips

- This option applies only to triggered subsystems and is enabled only if the Inport block resides in a triggered subsystem.
- Selecting this check box enables Simulink to resolve data dependencies among triggered subsystems that are part of a loop.
- Type `sl_subsys_semantics` at the MATLAB prompt for examples using latched inputs with triggered subsystems.
- The Inport block indicates that this option is selected by displaying `<Lo>`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Latch input for feedback signals of function-call subsystem outputs

Latch the value of the input to this subsystem and prevent this value from changing during the execution of the subsystem. For a single function call that is branched to invoke multiple function-call subsystems, this option allows you to break a loop formed by a signal fed back from one of these function-call subsystems into the other. A second functionality of this option is to prevent any change to the values of a feedback signal from a function-call subsystem that is invoked during the execution of this subsystem.

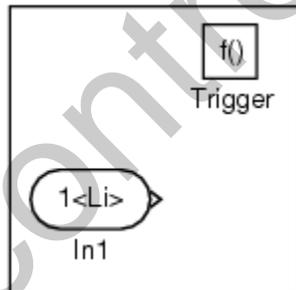

### Settings

**Default:** Off

- On  
Latch the input value.
- Off  
Do not latch the input value.

### Tips

- This parameter applies only to function-call subsystems and is enabled only if the Inport block resides in a function-call subsystem.
- This parameter ensures that the subsystem inputs, including those generated within the subsystem's context, do not change during execution of the subsystem.
- The Inport block indicates that this option is selected by displaying `<Li>`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Interpolate data

When loading data from the workspace, cause the block to linearly interpolate and extrapolate output at time steps for which no corresponding data exists.

To load discrete signal data from the workspace, in the Inport block dialog box:

- 1 Set the **Sample time** parameter to a discrete value, such as 2.
- 2 Clear the **Interpolate data** parameter.

Specifying the discrete sample time causes the simulation to have hit times exactly at those instances when the discrete data is sampled. You only need to specify the data values, not time values.

Turning interpolation off avoids unexpected data values at other simulation time points as a result of double precision arithmetic processing. For more information, see “Import Data to Test a Discrete Algorithm”.

### Settings

**Default:** On

On

When loading data from the workspace, cause the block to linearly interpolate and extrapolate output at time steps for which no corresponding data exists.

Off

When loading data from the workspace, do not cause the block to linearly interpolate or extrapolate output at time steps for which no corresponding data exists. Simulink uses the following interpolation and extrapolation:

- For time steps between the first specified data point and the last specified data point — zero-order hold
- For time steps before the first specified data point and after the last specified data point — ground value
- For variable-sized signals for time steps before the first specified data point — a NaN is logged for single or double data types and ground for other data types. For time steps after the last specified data point, uses ground values.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Connect Input

To import, visualize, and map signal and bus data to root-level inports, click this button. The Root Inport Mapper tool displays.

### Dependency

This button appears only if this block is a root inport block.

controlengineers.ir

## Output function call

Specify that the input signal is outputting a function-call trigger signal.

### Settings

**Default:** Off

On

Input signal is a function-call trigger signal.

Off

Input signal is not a function-call trigger signal.

### Tips

- Select this option if it is necessary for a current model to accept a function-call trigger signal when referenced in the top model.
- This feature is limited to an asynchronous function call.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Minimum

Specify the minimum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value that the block should output.

### Settings

**Default:** [] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see Simulink.BusElement.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Data type

Specify the output data type of the external input.

### Settings

**Default:** Inherit: auto

Inherit: auto

A rule that inherits a data type

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Data type is enumerated, for example, Enum: Basic Colors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example Simulink.NumericType

Do not specify a bus object as the expression.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right.

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Output as nonvirtual bus

Output a nonvirtual bus.

### Settings

**Default:** Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

### Tips

- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For referenced models, buses are single-rate. For details, see “Connect Multi-Rate Buses to Referenced Models”.
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus used in the referenced model.

### Dependencies

Selecting **Data type** > Bus: <object name> enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Unit (e.g., m, m/s<sup>2</sup>, N\*m)

Specify physical unit of the input signal to the block.

### Settings

**Default:** inherit

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a **Unit System Configuration** block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.

- If a **Unit System Configuration** block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Port dimensions (-1 for inherited)

Specify the dimensions of the input signal to the block.

### Settings

**Default:** -1

Valid values are:

-1	Dimensions are inherited from input signal
n	Vector signal of width n accepted
[m n]	Matrix signal having m rows and n columns accepted

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Variable-size signal

Specify the type of signals allowed into this port.

### Settings

**Default:** Inherit

Inherit

Allow variable-size and fixed-size signals.

No

Do not allow variable-size signals.

Yes

Allow only variable-size signals.

### Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

### Command-Line Information

**Parameter:** VarSizeSig

**Type:** character vector

**Value:** 'Inherit'| 'No' | 'Yes'

**Default:** 'Inherit'

## Sample time (-1 for inherited)

Specify the time interval between samples.

### Settings

**Default:** -1

To inherit the sample time, set this parameter to -1.

See “Specify Sample Time” in the online documentation for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Signal type

Specify the numeric type of the external input.

### Settings

**Default:** auto

auto

Accept either `real` or `complex` as the numeric type.

real

Specify the numeric type as a real number.

complex

Specify the numeric type as a complex number.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## Integrator, Integrator Limited

Integrate signal

### Library

Continuous

### Description

The Integrator block outputs the value of the integral of its input signal with respect to time.

The Integrator Limited block is identical to the Integrator block with the exception that the output of the block is limited based on the upper and lower saturation limits. See “Limiting the Integral” on page 1-862 for details.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- $u$  is the block input.
- $y$  is the block output.
- $x$  is the block state.
- $x_0$  is the initial condition of  $x$ .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use a number of different numerical integration methods to compute the Integrator

block's output, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

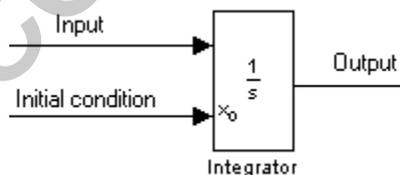

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

## Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as **internal** and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as **external**. An additional input port appears under the block input.

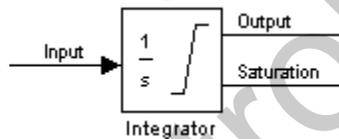

**Note** If the integrator limits its output (see “Limiting the Integral” on page 1-862), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

## Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

---

**Note:** For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

---

## Wrapping Cyclic States

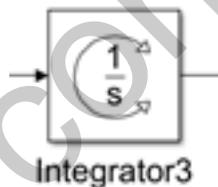

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches  $2\pi$  (or to  $-\pi$  when it reaches  $\pi$ , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & x \in [x_l, x_u) \text{ otherwise} \end{cases}$$

where:

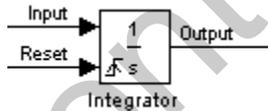

- $x_l$  is the lower value of the wrapped state.
- $x_u$  is the upper value of the wrapped state.
- $y$  is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

## Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select **rising** to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select **falling** to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select **either** to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.

- Select **level** to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select **level hold** to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

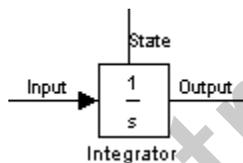

---

**Note:** To be compliant with the Motor Industry Software Reliability Association (MISRA<sup>®</sup>) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

---

## About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-866)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-867)

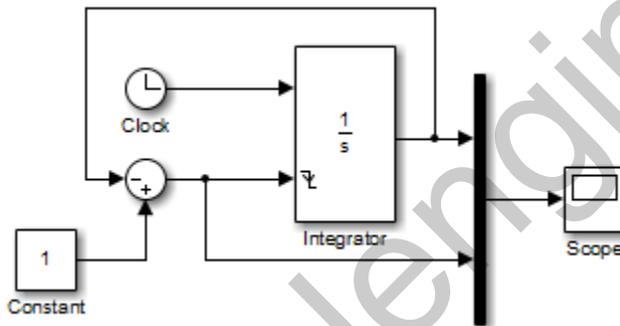

---

**Note** When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

---

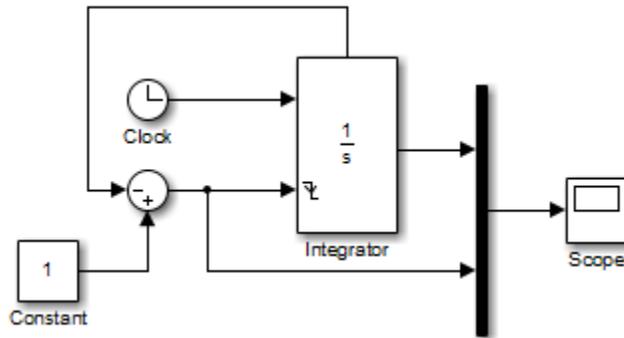

## Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

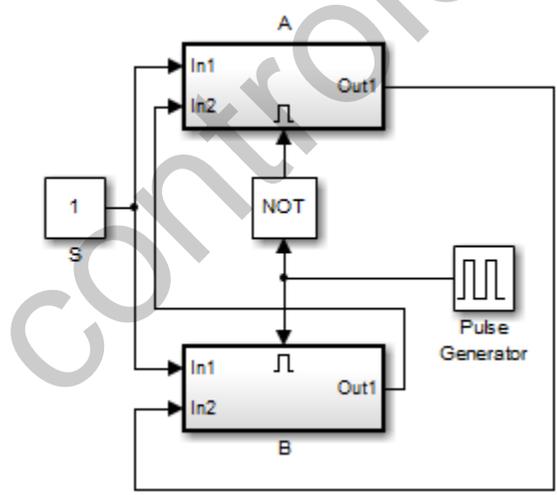

The following model uses the integrator's state port to avoid the algebraic loop.

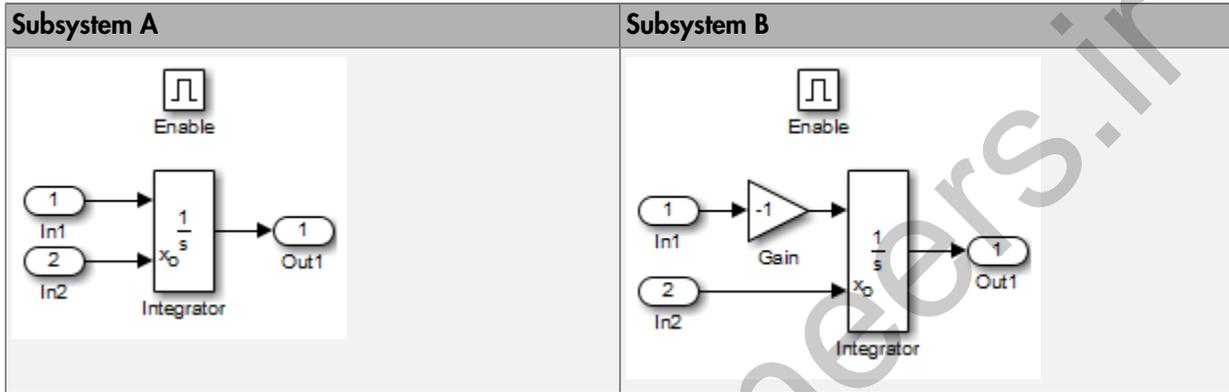

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

### Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

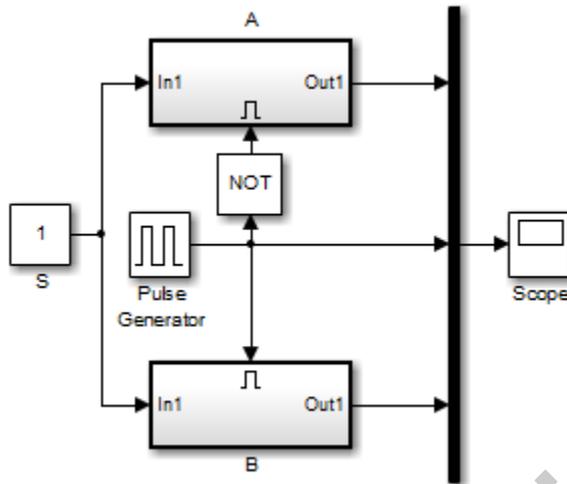

The enabled subsystems, A and B, contain the following blocks:

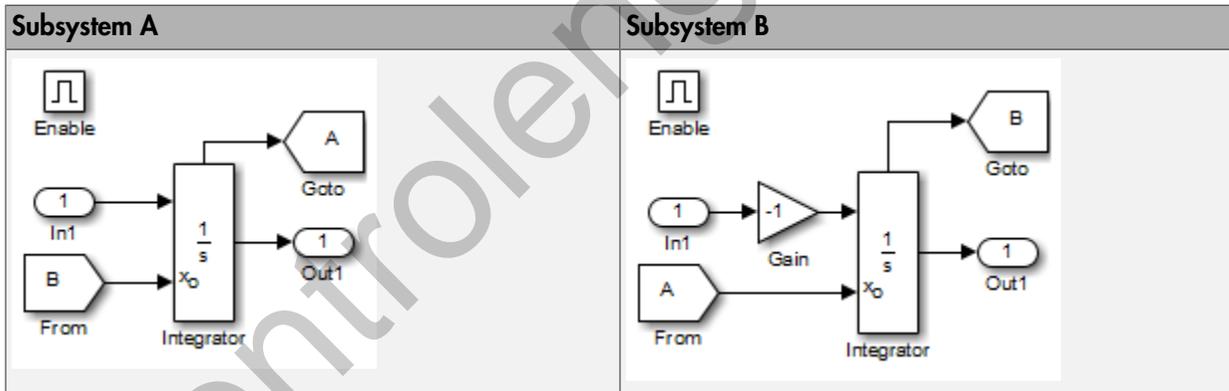

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

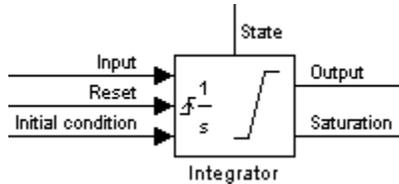

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

## Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

## Selecting All Options

When you select all options, the block icon looks like this.

## Data Type Support

The Integrator block accepts and outputs signals of type **double** on its data ports. The external reset port accepts signals of type **double** or **Boolean**.

## Parameters

### External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

### Settings

**Default:** none

none

Do not reset the state to initial conditions.

rising

Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.

**falling**

Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.

**either**

Reset the state when the reset signal changes from a zero to a nonzero value or changes sign.

**level**

Reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

**level hold**

Reset the state when the reset signal is nonzero at the current time step.

**Command-Line Information**

**Parameter:** ExternalReset

**Type:** character vector

**Value:** 'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'

**Default:** 'none'

## Initial condition source

Get the initial conditions of the states.

### Settings

**Default:** internal

internal

Get the initial conditions of the states from the **Initial condition** parameter.

external

Get the initial conditions of the states from an external block.

### Tips

Simulink software does not allow the initial condition of this block to be inf or NaN.

### Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter.

### Command-Line Information

**Parameter:** InitialConditionSource

**Type:** character vector

**Value:** 'internal' | 'external'

**Default:** 'internal'

## Initial condition

Specify the states' initial conditions.

### Settings

**Default:** 0

### Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

### Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

### Command-Line Information

**Parameter:** InitialCondition

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

## Limit output

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

### Settings

**Default:** Off

On

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Off

Do not limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

### Dependencies

This parameter enables **Upper saturation limit**.

This parameter enables **Lower saturation limit**.

### Command-Line Information

**Parameter:** LimitOutput

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Upper saturation limit

Specify the upper limit for the integral.

### Settings

**Default:** inf

**Minimum:** value of **Output minimum** parameter

**Maximum:** value of **Output maximum** parameter

### Dependencies

**Limit output** enables this parameter.

### Command-Line Information

**Parameter:** UpperSaturationLimit

**Type:** scalar or vector

**Value:** 'inf'

**Default:** 'inf'

Controlengineers.ir

## Lower saturation limit

Specify the lower limit for the integral.

### Settings

**Default:** `-inf`

**Minimum:** value of **Output minimum** parameter

**Maximum:** value of **Output maximum** parameter

### Dependencies

**Limit output** enables this parameter.

### Command-Line Information

**Parameter:** `LowerSaturationLimit`

**Type:** scalar or vector

**Value:** `'-inf'`

**Default:** `'-inf'`

Controlengineers.ir

## Wrap state

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

### Settings

**Default:** off

On

Enable wrap states between the **Wrapped state upper value** and **Wrapped state lower value** parameters.

If you specify **Wrapped state upper value** as `inf` and **Wrapped state lower value** as `-inf`, wrapping will never occur.

Off

Do not enable wrap states.

### Dependencies

This parameter enables **Wrapped state upper value**.

This parameter enables **Wrapped state lower value**.

### Command-Line Information

**Parameter:** WrapState

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Wrapped state upper value

Specify the upper value for the wrap state.

### Settings

Default: 'pi'

### Dependencies

Wrap state enables this parameter.

### Command-Line Information

Parameter: WrappedStateUpperValue

Type: scalar or vector

Value: '2\*pi'

Default: 'pi'

Controlengineers.ir

## Wrapped state lower value

Specify the lower value for the wrap state.

### Settings

Default:  $-\pi$

### Dependencies

Wrap state enables this parameter.

### Command-Line Information

Parameter: WrappedStateLowerValue

Type: scalar or vector

Value: '0'

Default: ' $-\pi$ '

Controlengineers.ir

## Show saturation port

Add a saturation output port to the block.

### Settings

**Default:** Off

On

Add a saturation output port to the block.

Off

Do not add a saturation output port to the block.

### Command-Line Information

**Parameter:** ShowSaturationPort

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

Controlengineers.ir

## Show state port

Add an output port to the block for the block's state.

### Settings

**Default:** Off

On

Add an output port to the block for the block's state.

Off

Do not add an output port to the block for the block's state.

### Command-Line Information

**Parameter:** ShowStatePort

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

Controlengineers.ir

## Absolute tolerance

Specify the absolute tolerance for computing block states.

### Settings

**Default:** auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

### Command-Line Information

**Parameter:** AbsoluteTolerance

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

## Ignore limit and reset when linearizing

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

### Settings

**Default:** Off

On

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

Off

Do not cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

### Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

### Command-Line Information

**Parameter:** IgnoreLimit

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

**Default:** On

On

Use zero crossings to detect and take a time step at any of the following events: reset, entering or leaving an upper saturation state, entering or leaving a lower saturation state.

Off

Do not use zero crossings to detect and take a time step at any of the following events: reset, entering or leaving an upper saturation state, entering or leaving a lower saturation state.

If you select this check box, **Limit output**, and zero-crossing detection for the model as a whole, the Integrator block uses zero crossings as described.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'on'

## State Name (e.g., 'position')

Assign a unique name to each state.

### Settings

**Default:** ' '

If this field is blank, no name assignment occurs.

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

### Command-Line Information

**Parameter:** ContinuousStateAttributes

**Type:** character vector

**Value:** ' ' | user-defined

**Default:** ' '

## Examples

The following example models show how to use the Integrator block:

- sldemo\_hardstop
- sldemo\_suspn

- sldemo\_wheel speed\_absbrake

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Yes, of the reset and external initial condition source ports
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled and you select the <b>Limit output</b> check box, one for detecting reset, one each to detect upper and lower saturation limits, and one when leaving saturation
Code Generation	Yes

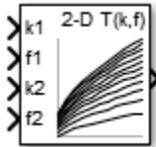

## See Also

Discrete-Time Integrator

Introduced before R2006a

## Interpolation Using Prelookup

Use precalculated index and fraction values to accelerate approximation of N-dimensional function

### Library

Lookup Tables

### Description

The Prelookup block calculates the index and interval fraction that specify how its input value  $u$  relates to the breakpoint data set. The Interpolation Using Prelookup block works best with the Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an  $n$ -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the  $n$ -D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility that can provide more efficient simulation and code generation. For more information, see “Efficiency of Performance” in the Simulink documentation.

### Supported Block Operations

To use the Interpolation Using Prelookup block, you specify a set of table data values directly on the dialog box or feed values into the  $T$  input port. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index and interval fraction values fed from Prelookup blocks. Labels for the index and interval fraction appear as  $k$  and  $f$  on the Interpolation Using Prelookup block icon.

When inputs for index and interval fraction...	The Interpolation Using Prelookup block...
Map to values in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not map to values in breakpoint data sets, but are within range	Interpolates appropriate table values, using the <b>Interpolation method</b> you select
Do not map to values in breakpoint data sets, and are out of range	Extrapolates the output value, using the <b>Extrapolation method</b> you select

## How The Block Interpolates a Subset of Table Data

You can use the **Number of sub-table selection dimensions** parameter to specify that interpolation occur only on a subset of the table data. To activate this interpolation mode, set this parameter to a positive integer. This value defines the number of dimensions to select, starting from the highest dimension of table data. Therefore, the value must be less than or equal to the **Number of table dimensions**.

Suppose that you have 3-D table data in your Interpolation Using Prelookup block. This behavior applies.

Number of Selection Dimensions	Action by the Block	Block Appearance
0	Interpolates the entire table and does not activate subtable selection	Does not change
1	Interpolates the first two dimensions and selects the third dimension	Displays an input port with the label <code>sel1</code> that you use to select and interpolate 2-D tables
2	Interpolates the first dimension and selects the second and third dimensions	Displays two input ports with the labels <code>sel1</code> and <code>sel2</code> that you use to select and interpolate 1-D tables

Subtable selection uses zero-based indexing. For an example of interpolating a subset of table data, type `sldemo_bpcheck` at the MATLAB command prompt.

## Data Type Support

The Interpolation Using Prelookup block accepts as input:

- Real signals of any numeric data type supported by Simulink software, except Boolean.
- Fixed-point data types for signals, table data, and intermediate results
- Bus data types

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Main Tab” on page 1-889
- “Data Types Tab” on page 1-894

## Main Tab

### Number of dimensions

Specify the number of dimensions that the table data must have. This value defines the number of independent variables for the table. Enter an integer between 1 and 30 into this field.

### Require index and fraction as bus

Input index and fraction signals to a bus port, with the index and fraction signals combined in a nonvirtual bus.

If you select this parameter, subtable selection ports continue to work in nonbus mode.

To enable the Prelookup block to supply input to the Interpolation Using Prelookup block, set:

- **Output selection** to Index and fraction as bus
- **Output to Bus:** <object name>, where <object name> must be a valid bus object name accessible to the model

## Specification

Specify whether to enter table data directly or use a lookup table object. If you set this parameter to:

- **Explicit values**, the **Source** and **Value** parameters are visible on the dialog box.
- **Lookup table object**, the **Name** parameter is visible on the dialog box.

### Source

Specify whether to enter table data in the dialog box or to inherit the data from an input port. This parameter is available when **Specification** is set to **Explicit values**. If you set **Source** to:

- **Dialog**, enter table data in the text box under **Value**.
- **Input port**, verify that an upstream signal supplies table data to the table input port.

### Value

If you set **Specification** to **Explicit values** and **Source** to **Dialog**, explicitly specify the table data.

You can edit the block diagram without specifying a correctly dimensioned matrix by entering an empty matrix (`[]`) or an undefined workspace variable in the **Value** edit field. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB).

If you set **Source** to **Input port**, verify that an upstream signal supplies table data to the T input port. The size of table data must match the **Number of table dimensions**. For this option, your block inherits table attributes from the T input port.

To edit lookup tables using the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables” in the Simulink documentation).

### Name

Specify the name of an existing `Simulink.LookupTable` object. An existing lookup table object references Simulink breakpoint objects.

### Interpolation method

Select **Flat**, **Nearest**, or **Linear**. See “Interpolation Methods” in the Simulink documentation for more information.

### Extrapolation method

Select **Clip** or **Linear**. See “Extrapolation Methods” in the Simulink documentation for more information. The **Extrapolation method** parameter is visible only when you select **Linear** as the **Interpolation method** parameter.

The Interpolation Using Prelookup block does not support **Linear** extrapolation when the input or output signals specify integer or fixed-point data types.

### Valid index input may reach last index

Specify how block inputs for index (**k**) and interval fraction (**f**) access the last elements of *n*-dimensional table data. Index values are zero based.

Check Box	Block Behavior
Selected	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> <li>• <b>k</b> indexes the last table element in the corresponding dimension</li> <li>• <b>f</b> is 0</li> </ul>
Cleared	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> <li>• <b>k</b> indexes the next-to-last table element in the corresponding dimension</li> <li>• <b>f</b> is 1</li> </ul>

This check box is visible only when:

- **Interpolation method** is **Linear**.
- **Extrapolation method** is **Clip**.

---

**Tip:** When you select **Valid index input may reach last index** for an Interpolation Using Prelookup block, you must also select **Use last breakpoint for input at or above upper limit** for all **Prelookup** blocks that feed it. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

---

### Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input  $k$  or  $f$  is out of range. Options include:

- **None** — Simulink software takes no action.
- **Warning** — Simulink software displays a warning and continues the simulation.
- **Error** — Simulink software terminates the simulation and displays an error.

**Remove protection against out-of-range index in generated code**

Specify whether or not to include code that checks for out-of-range index inputs.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range index inputs.  When the input $k$ or $f$ is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range index inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to **Error**.
- 3 Simulate the model in normal mode.

- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

---

**Note:** When you select the **Remove protection against out-of-range index in generated code** check box and the input k or f is out-of-range, the behavior is undefined for generated code and simulations using **accelerator mode**.

---

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

This check box has no effect on the generated code when one of the following is true:

- The Prelookup block feeds index values to the Interpolation Using Prelookup block.

Because index values from the Prelookup block are always valid, no check code is necessary.

- The data type of the input k restricts the data to valid index values.

For example, unsigned integer data types guarantee nonnegative index values. Therefore, unsigned input values of k do not require check code for negative values.

### **Number of sub-table selection dimensions**

Specify the number of dimensions of the subtable that the block uses to compute the output. Follow these rules:

- To enable subtable selection, enter a positive integer.

This integer must be less than or equal to the **Number of table dimensions**.

- To disable subtable selection, enter 0 to interpolate the entire table.

For more information, see “How The Block Interpolates a Subset of Table Data” on page 1-888.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Data Types Tab

---

**Note:** The parameters for table attributes (data type, minimum, and maximum) are not available when you set **Source** to **Input port**. In this case, the block inherits all table attributes from the T input port.

---

### Table data > Data Type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, **Inherit: Same as output**
- The name of a built-in data type, for example, **single**
- The name of a data type object, for example, a **Simulink.NumericType** object
- An expression that evaluates to a data type, for example, **fixdt(1,16,0)**

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

---

**Tip:** Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two Interpolation Using Prelookup blocks with different output data types

- Sharing of custom storage table data in Simulink Coder generated code for blocks with different output data types
- 

### Table data > Minimum

Specify the minimum value for table data. The default value is [ ] (unspecified).

### Table data > Maximum

Specify the maximum value for table data. The default value is [ ] (unspecified).

### Intermediate results > Data Type

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the intermediate results data type.

---

**Tip:** Use this parameter to specify higher precision for internal computations than for table data or output data.

---

### Output > Data Type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Output > Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output > Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Internal rule priority

Specify the internal rule for intermediate calculations. Select **Speed** for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

### Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function in the mask field.

### Saturate on integer overflow

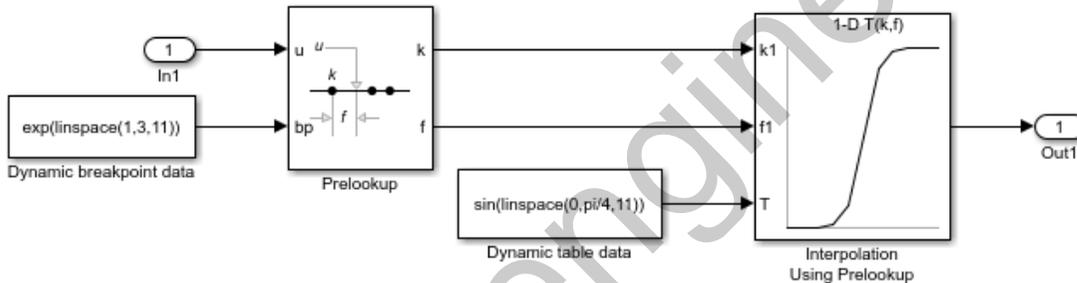

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Examples

### Prelookup with External Breakpoint Specification

In the following model, a Constant block feeds the table data values to the T input port of the Interpolation Using Prelookup block.

The Interpolation Using Prelookup block inherits the following table attributes from the T input port:

Table Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Similarly, a Constant block feeds the breakpoint data set to the bp input port of the Prelookup block, which inherits the following breakpoint attributes:

Breakpoint Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoint and table data as single-precision, floating-point data. Using a lower-precision data type to store breakpoint and table data reduces the memory requirement.

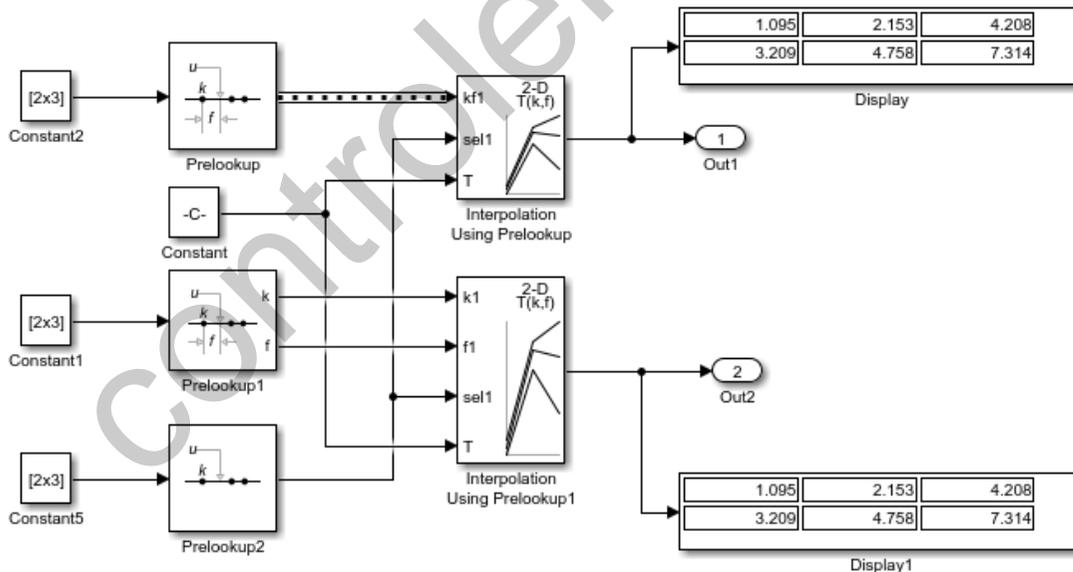

For other examples, see “Prelookup and Interpolation Blocks” in the Simulink documentation.

## Use a Bus for Index and Fraction

You can use a bus object to specify the index ( $k$ ) and fraction ( $f$ ) in the Prelookup block and then use that bus as input to an Interpolation Using Prelookup block. This example shows how to use a bus signal and how to get the same results without using a bus object.

Open the model and simulate it.

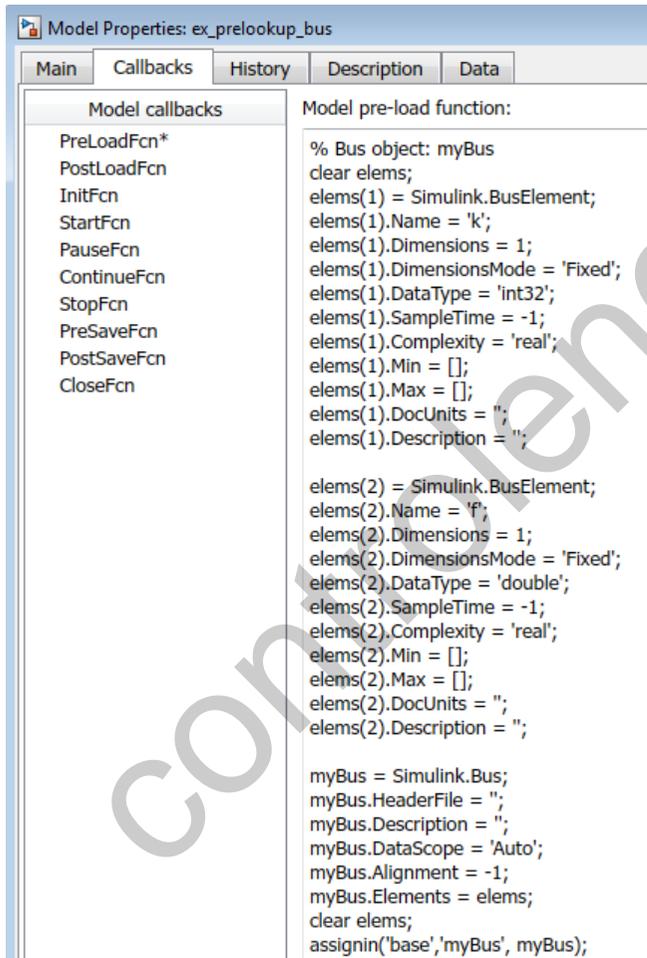

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
    'examples','ex_prelookup_bus.slx'))
sim('ex_prelookup_bus')
```

At the top of the model, open the **Prelookup** block parameters dialog box. In the **Main** tab, note that **Output selection** is set to **Index** and **fraction** as **bus**.

In the **Data Types** tab, note that **Output** is set to **Bus: myBus**.

In the Simulink Editor, select **File > Model Properties** and open the **Callbacks** tab. The code defines the bus object **myBus**, which specifies the index as the first bus element and the fraction as the second element.

In the Interpolation Using Prelookup block parameters dialog box, in the **Main** tab, note that **Require index and fraction as bus** check box is selected. That option configures the block to use the bus output from the Prelookup block.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

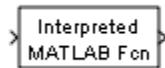

## See Also

Prelookup

Introduced in R2006b

# Interpreted MATLAB Function

Apply MATLAB function or expression to input

## Library

User-Defined Functions

## Description

The Interpreted MATLAB Function block applies the specified MATLAB function or expression to the input. The output of the function must match the output dimensions of the block.

Some valid expressions for this block are:

```
sin
atan2(u(1), u(2))
u(1)^u(2)
```

---

**Note** This block is slower than the Fcn block because it calls the MATLAB parser during each integration step. Consider using built-in blocks (such as the Fcn block or the Math Function block) instead. Alternatively, you can write the function as a MATLAB S-function or MEX-file S-function, then access it using the S-Function block.

---

## Data Type Support

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

## Parameters

### MATLAB function

Specify the function or expression. If you specify a function only, it is not necessary to include the input argument in parentheses.

### Output dimensions

Specify the dimensions of the block output signal, for example, **2** for a two-element vector. The output dimensions must match the dimensions of the value returned by the function or expression in the **MATLAB function** field.

Specify **-1** to inherit the dimensions from the output of the specified function or expression. To determine the output dimensions, Simulink runs the function or expression once before simulation starts.

---

**Note:** If you specify **-1** for this parameter and your function has persistent variables, then the variables might update before the simulation starts. If you need to use persistent variables, consider setting this parameter to a value other than **-1**.

---

### Output signal type

Specify the output signal type of the block as **real**, **complex**, or **auto**. A value of **auto** sets the output type to be the same as the type of the input signal.

### Collapse 2-D results to 1-D

Select this check box to output a 2-D array as a 1-D array containing the 2-D array's elements in column-major order.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than **-1**. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Characteristics

Data Types	Double
------------	--------

Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	No

**Introduced in R2011a**

Controlengineers.ir

## Interval Test

Determine if signal is in specified interval

## Library

Logic and Bit Operations

## Description

The Interval Test block outputs TRUE if the input is between the values specified by the **Lower limit** and **Upper limit** parameters. The block outputs FALSE if the input is outside those values. The output of the block when the input is equal to the **Lower limit** or the **Upper limit** is determined by whether the boxes next to **Interval closed on left** and **Interval closed on right** are selected in the dialog box.

## Data Type Support

The Interval Test block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

In this case, the **Upper limit** and **Lower limit** values must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Interval closed on right

When you select this check box, the **Upper limit** is included in the interval for which the block outputs TRUE.

### Upper limit

The upper limit of the interval for which the block outputs TRUE.

### Interval closed on left

When you select this check box, the **Lower limit** is included in the interval for which the block outputs TRUE.

### Lower limit

The lower limit of the interval for which the block outputs TRUE.

### Output data type

Select the output data type: `boolean` or `uint8`.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Interval Test Dynamic

Introduced before R2006a

# Interval Test Dynamic

Determine if signal is in specified interval

## Library

Logic and Bit Operations

## Description

The Interval Test Dynamic block outputs TRUE if the input is between the values of the external signals up and lo. The block outputs FALSE if the input is outside those values. The output of the block when the input is equal to the signal up or the signal lo is determined by whether the boxes next to **Interval closed on left** and **Interval closed on right** are selected in the dialog box.

## Data Type Support

The Interval Test Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

In this case, all inputs must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Interval closed on right

When you select this check box, the value of the signal connected to the block's "up" input port is included in the interval for which the block outputs TRUE.

### Interval closed on left

When you select this check box, the value of the signal connected to the block's "lo" input port is included in the interval for which the block outputs TRUE.

### Output data type

Select the output data type: boolean or uint8.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Knob

Set value on dial to tune parameters or variables

## Library

Dashboard

## Description

The Knob block enables you to control tunable parameters and variables in your model during simulation.

To control a tunable parameter or variable using the Knob block, double-click the Knob block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

The tick range determines the continuous values generated for the tunable parameter or variable. You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

## Limitations

The Knob block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

Limitation	Workaround
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### Scale Type

Type of scale to use for tuning.

### Settings

**Default:** Linear

Linear

Use linear scale.

Log

Use logarithmic scale.

## Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

## Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

## Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

## Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Lamp

Display color that reflects input value

## Library

Dashboard

## Description

The Lamp block displays distinct input values from connected signals during simulation on a colored lamp.

To display data from a signal on the Lamp block, double-click the Lamp block to open the dialog box. Select a signal in the model canvas. The signal appears in the dialog box **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal to the block.

You can add or remove input values that are indicated by the Lamp block using the **States** table.

## Limitations

The Lamp block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to a Lamp block, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the Lamp block and reconnect the signal.

External mode simulation does not support the Lamp block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a signal to connect and display.

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

### Settings

The table has a row for the signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### States

State values and colors indicated on the lamp.

The states defined in the table determine the distinct input values indicated by the colored lamp, which are represented by the **Color** field. You can modify the input value states by editing the **State** and **Color** in the table.

To add a state, click the + button, enter the **State** value, and select a **Color**.

To remove a state, select the state in the table, and click the - button.

### Settings

**Default:** 0 and undefined

The **undefined** state is indicated when values that are not defined in the states table are input into the Lamp block.

## Label

Position of the block label or instructional text if the block is not connected.

### Settings

#### Default: Top

##### Top

Show the label at the top of the block.

##### Bottom

Show the label at the bottom of the block.

##### Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Level-2 MATLAB S-Function

Use Level-2 MATLAB S-function in model

### Library

User-Defined Functions

### Description

This block allows you to use a Level-2 MATLAB S-function (see “Write Level-2 MATLAB S-Functions”) in a model. To do this, create an instance of this block in the model. Then enter the name of the Level-2 MATLAB S-function in the **S-function name** field of the block's parameter dialog box.

---

**Note:** Use the S-Function block to include a Level-1 MATLAB S-function in a block.

---

If the Level-2 MATLAB S-function defines any additional parameters, you can enter them in the **Parameters** field of the block's parameter dialog box. Enter the parameters as MATLAB expressions that evaluate to their values in the order defined by the MATLAB S-function. Use commas to separate each expression.

If a model includes a Level-2 MATLAB S-Function block, and an error occurs in the S-function, the Level-2 MATLAB S-Function block displays MATLAB stack trace information for the error in a dialog box. Click **OK** to close the dialog box.

### Data Type Support

Depends on the MATLAB file that defines the behavior of a particular instance of this block.

## Parameters

### S-function name

Specify the name of a MATLAB function that defines the behavior of this block. The MATLAB function must follow the Level-2 standard for writing MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” for details).

### Parameters

Specify values of the parameters of this block.

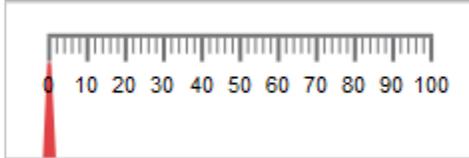

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Depends on the MATLAB S-function
Direct Feedthrough	Depends on the MATLAB S-function
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced in R2010b**

## Linear Gauge

Display input value on linear scale

## Library

Dashboard

## Description

The Linear Gauge block displays connected signals during simulation on a linear scale.

To view data from a signal on the Linear Gauge block, double-click the Linear Gauge block to open the dialog box. Select a signal in the model canvas. The signal appears in the dialog box **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal to the block.

You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

You can also add scale colors that appear on the outside of the Linear Gauge block scale using the **Scale Colors** table.

## Limitations

The Linear Gauge block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to any dashboard gauge, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the gauge and reconnect the signal.

External mode simulation does not support the Linear Gauge block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a signal to connect and display.

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

### Settings

The table has a row for the signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

## Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

## Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

## Scale Colors

Specify ranges of color bands on the outside of the scale. Specify the minimum and maximum color range to display on the gauge.

## Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

Controlengineers.ir

## Logical Operator

Perform specified logical operation on input

### Library

Logic and Bit Operations

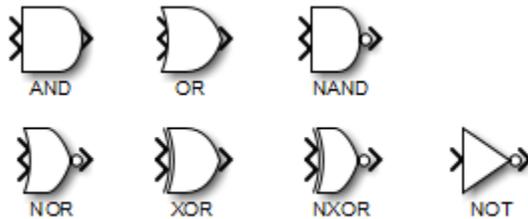

### Description

The Logical Operator block performs the specified logical operation on its inputs. An input value is TRUE (1) if it is nonzero and FALSE (0) if it is zero.

You select the Boolean operation connecting the inputs with the **Operator** parameter list. If you select **rectangular** as the **Icon shape** property, the block updates to display the name of the selected operator. The supported operations are given below.

Operation	Description
AND	TRUE if all inputs are TRUE
OR	TRUE if at least one input is TRUE
NAND	TRUE if at least one input is FALSE
NOR	TRUE when no inputs are TRUE
XOR	TRUE if an odd number of inputs are TRUE
NXOR	TRUE if an even number of inputs are TRUE
NOT	TRUE if the input is FALSE

If you select **distinctive** as the **Icon shape**, the block's appearance indicates its function. Simulink software displays a distinctive shape for the selected operator, conforming to the IEEE Standard Graphic Symbols for Logic Functions:

The number of input ports is specified with the **Number of input ports** parameter. The output type is specified with the **Output data type** parameter. An output value is 1 if TRUE and 0 if FALSE.

---

**Note** The output data type should represent zero exactly. Data types that satisfy this condition include signed and unsigned integers, and any floating-point data type.

---

The size of the output depends on input vector size and the selected operator:

- If the block has more than one input, any nonscalar inputs must have the same dimensions. For example, if any input is a 2-by-2 array, all other nonscalar inputs must also be 2-by-2 arrays.

Scalar inputs are expanded to have the same dimensions as the nonscalar inputs.

If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the specified operation is AND and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top left element is the result of applying AND to the top left elements of the inputs, etc.

- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector. The output is always a scalar.
- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the logical complements of the input vector elements.

When configured as a multi-input XOR gate, this block performs an addition- modulo-two operation as mandated by the IEEE Standard for Logic Elements.

## Data Type Support

The Logical Operator block accepts real signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

Controlengineers.ir

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Operator

Select logical operator to apply to block inputs.

### Settings

**Default:** AND

AND

TRUE if all inputs are TRUE

OR

TRUE if at least one input is TRUE

NAND

TRUE if at least one input is FALSE

NOR

TRUE when no inputs are TRUE

XOR

TRUE if an odd number of inputs are TRUE

NXOR

TRUE if an even number of inputs are TRUE

NOT

TRUE if the input is FALSE

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Number of input ports

Specify number of block inputs.

### Settings

**Default:** 2

- The value must be appropriate for the selected operator.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Icon shape

Specify shape of the block icon.

### Settings

**Default:** rectangular

rectangular

Result in a rectangular block that displays the name of the selected operator.

distinctive

Use the graphic symbol for the selected operator as specified by the IEEE standard.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Require all inputs and output to have the same data type

Require all inputs and the output to have the same data type.

### Settings

**Default:** Off

On

Require all inputs and the output to have the same data type.

Off

Do not require all inputs and the output to have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Output data type

Specify the output data type.

### Settings

**Default:** boolean

**Inherit:** Logical (see Configuration Parameters: Optimization)

Uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

---

**Note:** This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

---

`boolean`

Specifies output data type is `boolean`.

`fixdt(1,16)`

Specifies output data type is `fixdt(1,16)`.

`<data type expression>`

Uses the name of a data type object, for example, `Simulink.NumericType`.

---

**Tip:** To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

---

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Mode

Select the category of data to specify.

### Settings

**Default:** Built in

Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables **Logical** (see **Configuration Parameters: Optimization**).

Built in

Specifies built-in data types. Selecting **Built in** enables **boolean**.

Fixed point

Specifies fixed-point data types.

Expression

Specifies expressions that evaluate to data types.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Integer

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

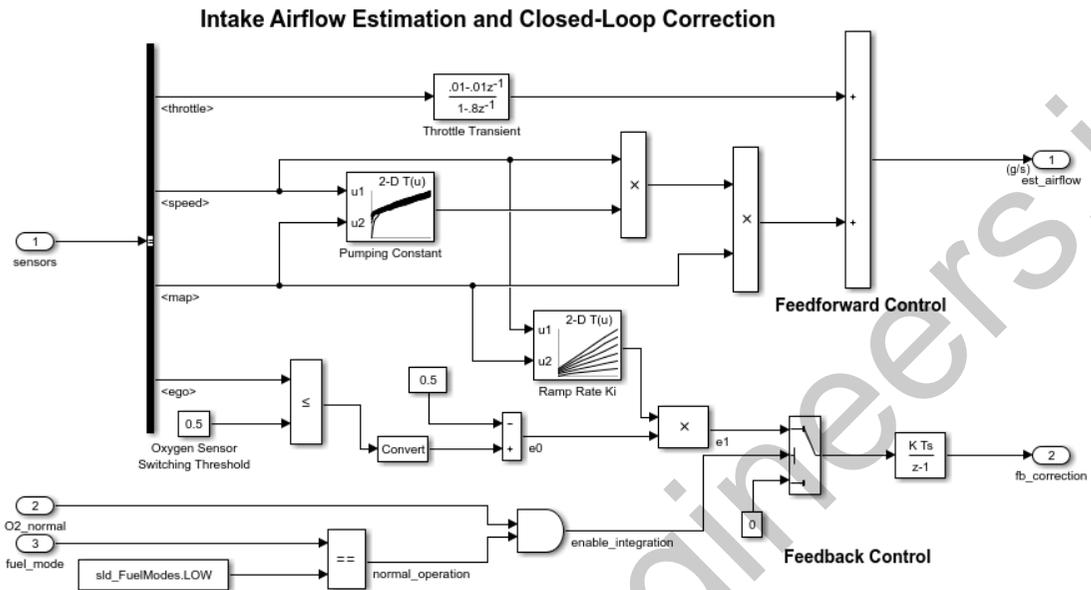

### See Also

See “Specifying a Fixed-Point Data Type”.

## Examples

### Logical Operator Block: AND Operator

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses a Logical Operator block as an AND operator:

The output of the Logical Operator block (the `enable_integration` signal) feeds into the control port of a Switch block that activates feedback control.

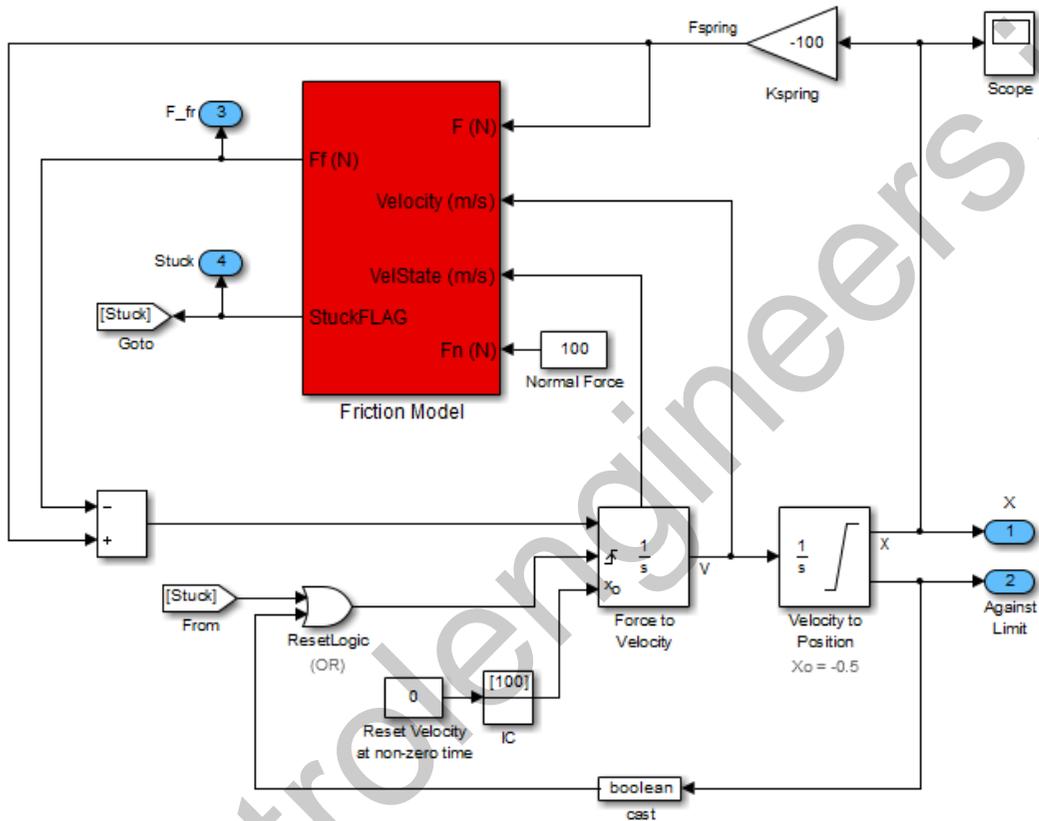

When the Logical Operator block output is...	Feedback control...
1	Occurs
0	Does not occur

### Logical Operator Block: OR Operator

In the `sldemo_hardstop` model, the Logical Operator block appears as an OR operator:

?

### Friction Model with Hard Stops

The output of the Logical Operator block feeds into the trigger port of an Integrator block to control whether velocity resets to the initial condition.

When the Logical Operator block output changes...	The Integrator block...
From 0 to 1	Resets the velocity
From 1 to 0	Does not reset velocity

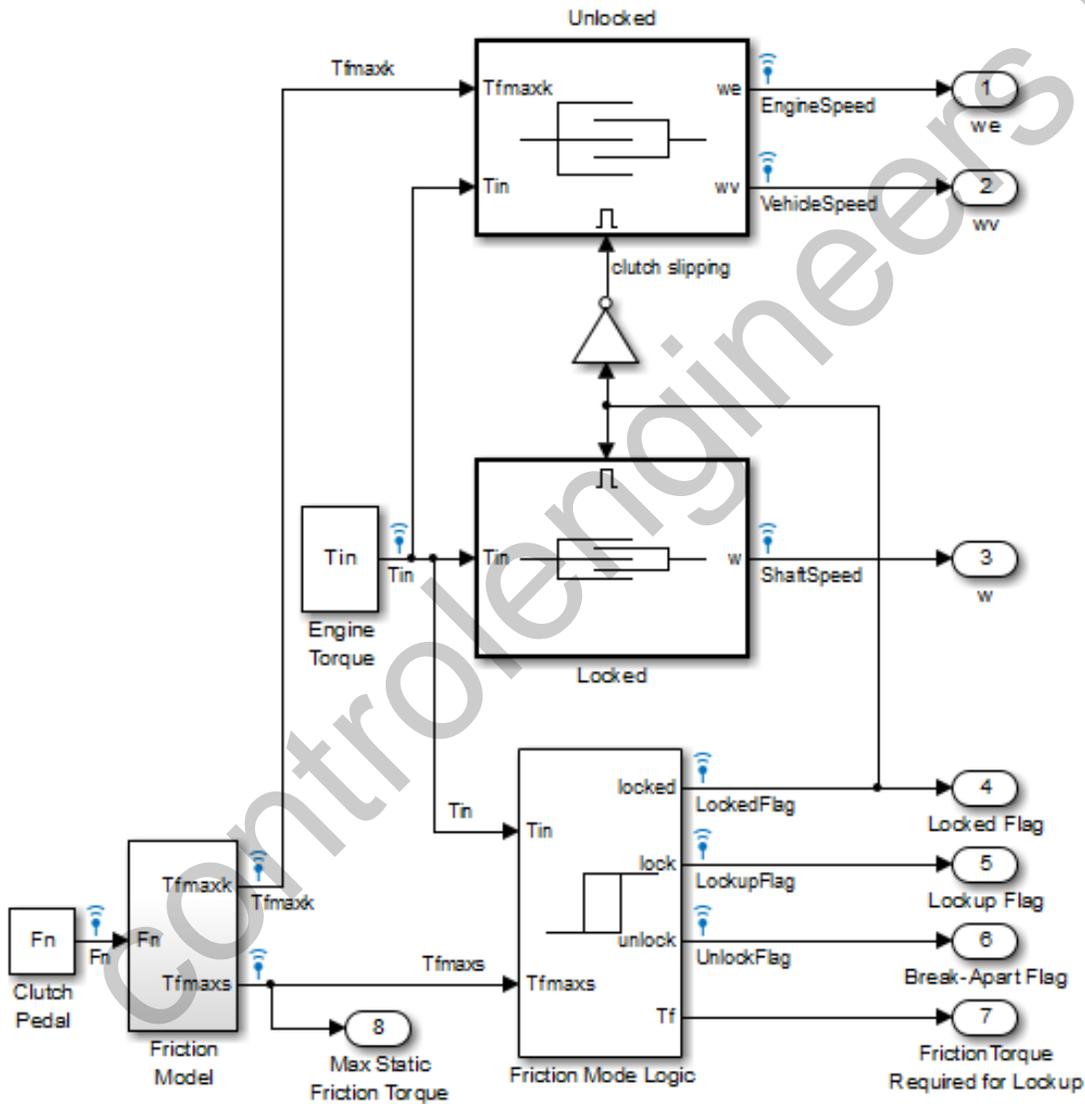

## Logical Operator Block: NOT Operator

In the sldemo\_clutch model, the Logical Operator block appears as a NOT operator:

controlengineers.ir

### Building a Clutch Lock-Up Model An Example of Enabled Subsystems

The output of the Logical Operator block (the `clutch_slipping` signal) feeds into the trigger port of an enabled subsystem.

When the Logical Operator block outputs...	The Unlocked subsystem is...
1	Enabled
0	Disabled

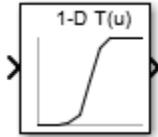

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## 1-D Lookup Table

Approximate one-dimensional function

### Library

Lookup Tables

### Description

The 1-D Lookup Table block is a one-dimensional version of the n-D Lookup Table block.

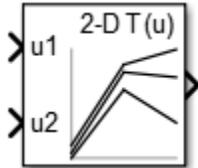

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced in R2011a

## 2-D Lookup Table

Approximate two-dimensional function

### Library

Lookup Tables

### Description

The 2-D Lookup Table block is a two-dimensional version of the n-D Lookup Table block.

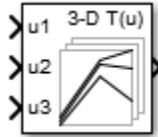

### Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced in R2011a

## n-D Lookup Table

Approximate N-dimensional function

### Library

Lookup Tables

### Description

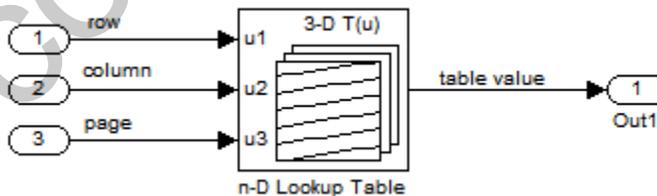

#### Supported Block Operations

The n-D Lookup Table block evaluates a sampled representation of a function in  $N$  variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function  $F$  can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear, and cubic-spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.

## Specification of Breakpoint and Table Data

The following block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

**Tip:** Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

## How the Block Generates Output

The n-D Lookup Table block generates output by looking up or estimating table values based on the input values:

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the <b>Interpolation method</b> you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the <b>Extrapolation method</b> you select

## Other Blocks That Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value  $k$  and you want the  $k$ th element of a table,  $y = \text{table}(k)$ , interpolation is unnecessary.

## Data Type Support

The n-D Lookup Table block supports all numeric data types that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

For cubic spline interpolation and linear extrapolation modes, the following parameters must use the same floating-point type:

- Table data
- Breakpoints
- Fraction
- Intermediate results
- Output

Inputs for indexing must be real, but table data can be complex.

## Parameters

- “Table and Breakpoints Tab” on page 1-946
- “Algorithm Tab” on page 1-949
- “Data Types Tab” on page 1-954

## Table and Breakpoints Tab

Number of table dimensions

Enter the number of dimensions of the lookup table by specifying an integer from 1 to 30. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

### Data specification

From the list, select:

- **Table and breakpoints** — Specify the table data and breakpoints. Selecting this option enables these parameters:
  - **Table data**
  - **Breakpoints specification**
  - **Breakpoints 1**
  - **Breakpoints 2**
  - **Breakpoints 3**
  - **Edit table and breakpoints**
- **Lookup table object** — Use an existing lookup table (Simulink.LookupTable) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

### Name

Enter the name of the lookup table (Simulink.LookupTable) object.

### Table data

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as [ ]) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB) in the MATLAB online documentation.

### Breakpoints specification

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to **Explicit values** and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to **Even spacing** and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

### First point

Specify the first point in your evenly spaced breakpoint data. This parameter is available when **Breakpoints specification** is set to **Even spacing**.

### Spacing

Specify the spacing between points in your evenly-spaced breakpoint data. This parameter is available when **Breakpoints specification** is set to **Even spacing**.

### Breakpoints

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to **Even spacing**, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.
- If you set **Breakpoints specification** to **Explicit values**, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

### Edit table and breakpoints

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Algorithm Tab

### Interpolation method

Select **Flat**, **Nearest**, **Linear**, or **Cubic spline**. See “Interpolation Methods” in the Simulink documentation for more information.

If you select **Cubic spline**, the block supports only scalar signals. The other interpolation methods support nonscalar signals.

### Extrapolation method

Select **Clip**, **Linear**, or **Cubic spline**. See “Extrapolation Methods” in the Simulink documentation for more information.

To select **Cubic spline** for **Extrapolation method**, you must also select **Cubic spline** for **Interpolation method**.

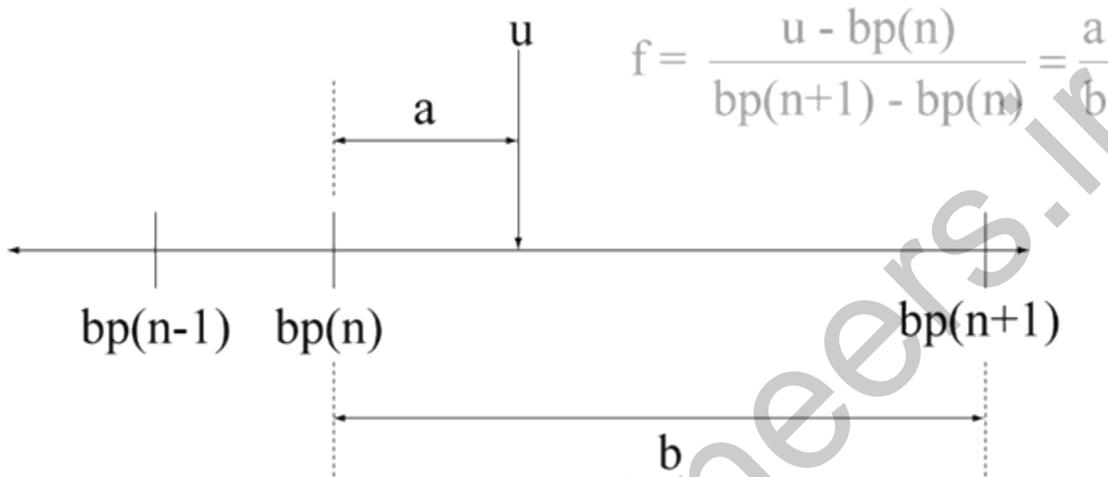

### Use last table value for inputs at or above last breakpoint

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is larger than the last element of the breakpoint data. This parameter is visible only when:

- **Interpolation method** is **Linear**.
- **Extrapolation method** is **Clip**.

Check Box	Block Uses Index Of The...	Interval Fraction
Selected	Last element of breakpoint data on the <b>Table and Breakpoints</b> tab	0
Cleared	Next-to-last element of breakpoint data on the <b>Table and Breakpoints</b> tab	1

Given an input  $u$  within range of a breakpoint set  $bp$ , the interval fraction  $f$ , in the range  $0 \leq f \leq 1$ , is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input  $u$  is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this checkbox, the index is that of the next-to-last element (4) and the interval fraction is 1.

#### Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input is out of range.

Options include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

#### Remove protection against out-of-range input in generated code

Specify whether or not to include code that checks for out-of-range breakpoint input values.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for	For code efficiency

Check Box	Result	When to Use
	out-of-range breakpoint inputs.  When the input k or f is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	
Cleared	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

---

**Note:** When you select the **Remove protection against out-of-range index in generated code** check box and the input k or f is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

---

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

### Index search method

Select **Evenly spaced points**, **Linear search**, or **Binary search**. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting **Evenly spaced points** to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

- For unevenly spaced breakpoint sets, follow these guidelines:
  - If input signals do not vary much between time steps, selecting **Linear search** with **Begin index search using previous index result** produces the best performance.
  - If input signals jump more than one or two table intervals per time step, selecting **Binary search** produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

---

**Note:** The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
  - The index search method is **Evenly spaced points**.
- 

### Begin index search using previous index result

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the

interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

### Use one input port for all input data

Select this check box to use only one input port that expects a signal that is N elements wide for an N-dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

---

**Note:** When you select this check box, one input port with the label `u` appears on the block.

---

### Support tunable table size in code generation

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code.

If you set **Interpolation method** to **Cubic spline**, this check box is not available.

### Maximum indices for each dimension

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Here are some examples of valid specifications:

- `[4 6]` for a 5-by-7 table
- `[int8(2) int16(5) int32(9)]` for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-959.

This parameter is available when you select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

## Data Types Tab

---

**Note:** The dialog box can expand to show additional data type options. Up to 30 breakpoint data type specifications can appear.

---

### Table data > Data Type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

---

**Tip:** Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
  - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
  - Sharing of custom storage table data in the generated code for blocks with different output data types
- 

### Table data > Minimum

Specify the minimum value for table data. The default value is [ ] (unspecified).

### Table data > Maximum

Specify the maximum value for table data. The default value is [ ] (unspecified).

### Breakpoints > Data Type

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the breakpoint data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation for more information.

---

**Tip:** Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
  - Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
  - Sharing of custom storage breakpoint data in the generated code for blocks with different input data types
- 

### **Breakpoints > Minimum**

Specify the minimum value that a set of breakpoint data can have. The default value is [ ] (unspecified).

### **Breakpoints > Maximum**

Specify the maximum value that a set of breakpoint data can have. The default value is [ ] (unspecified).

### **Fraction > Data Type**

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`

- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the fraction data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation for more information.

### Intermediate results > Data Type

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the intermediate results data type.

---

**Tip:** Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

---

### Output > Data Type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” for more information.

### **Output > Minimum**

Specify the minimum value that the block outputs. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### **Output > Maximum**

Specify the maximum value that the block outputs. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### **Internal rule priority**

Specify the internal rule for intermediate calculations. Select **Speed** for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

### **Require all inputs to have the same data type**

Select to require all inputs to have the same data type.

### **Lock data type settings against changes by the fixed-point tools**

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Fixed-Point Tool” (Fixed-Point Designer) and “Preparation for Fixed-Point Conversion” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

### Integer rounding mode

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

---

**Tip:** If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

---

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Examples

### Interpolation and Extrapolation Behavior

For an example that illustrates linear interpolation and extrapolation methods of this block, see “Create a Logarithm Lookup Table” in the Simulink documentation.

For an example of entering breakpoint and table data, see “Entering Data in a Block Parameter Dialog Box” in the Simulink documentation.

### Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: s1LookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object s1Bus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
s1LookupTable = s1Bus1;
s1LookupTable.Elements(1).DataType = 'uint32';
```

- The following block parameters apply in the n-D Lookup Table block dialog box:

Parameter	Value
Number of table dimensions	2
Table data	p.Table

Parameter	Value
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this:

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} s1LookupTable;
```

The generated `model.c` file contains code that looks something like this:

```
/* Exported block parameters */
s1LookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
        p.MaxIdx, p.MaxIdx[0] + 1U);
}
```

```

/* Output: '<Root>/Out1' */
ex_lut_nd_tunable_table_Y.Out1 = Y;

/* tid is required for a uniform function interface.
 * Argument tid is not used in the function. */
UNUSED_PARAMETER(tid);
}
    
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block

# Lookup Table Dynamic

Approximate one-dimensional function using dynamic table

## Library

Lookup Tables

## Description

### How This Block Differs from Other Lookup Table Blocks

The Lookup Table Dynamic block computes an approximation of a function  $y = f(x)$  using `xdat` and `ydat` vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Using the Lookup Table Dynamic block, you can change the table data without stopping the simulation. For example, you can incorporate new table data if the physical system you are simulating changes.

### Inputs for Breakpoint and Table Data

The `xdat` vector is the breakpoint data, which must be *strictly monotonically increasing*. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

The `ydat` vector is the table data, which is an evaluation of the function at the breakpoint values.

---

**Note:** The inputs to `xdat` and `ydat` cannot be scalar (one-element array) values. If you provide a scalar value to either of these inputs, you see an error upon simulation. Provide a 1-by-n vector to both the `xdat` and `ydat` inputs.

---

## Lookup Table Definition

You define the lookup table by feeding `xdat` and `ydat` as 1-by-n vectors to the block. To reduce ROM usage in the generated code for this block, you can use different data types for `xdat` and `ydat`. However, these restrictions apply:

- The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.
- The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

---

**Tip:** Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

---

## How the Block Generates Output

The block uses the input values to generate output using the method you select for **Lookup Method**:

Lookup Method	Block Action
Interpolation-Extrapolation	Performs linear interpolation and extrapolation of the inputs. <ul style="list-style-type: none"> <li>• If the input matches a breakpoint, the output is the corresponding element in the table data.</li> <li>• If the input does not match a breakpoint, the block performs linear interpolation between two elements of the table to determine the output. If the input falls outside the range of breakpoint values, the block extrapolates using the first two or last two points.</li> </ul>

Lookup Method	Block Action
	<b>Note:</b> If you select this lookup method, Simulink Coder software cannot generate code for this block.
Interpolation-Use End Values (default)	Performs linear interpolation but does not extrapolate outside the end points of the breakpoint data. Instead, the block uses the end values.
Use Input Nearest	Finds the element in <code>xdat</code> nearest the current input. The corresponding element in <code>ydat</code> is the output.
Use Input Below	Finds the element in <code>xdat</code> nearest and below the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> below the current input, the block finds the nearest element.
Use Input Above	Finds the element in <code>xdat</code> nearest and above the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> above the current input, the block finds the nearest element.

---

**Note** The Use Input Nearest, Use Input Below, and Use Input Above methods perform the same action when the input  $x$  matches a breakpoint value.

---

Some continuous solvers subdivide the simulation time span into major and minor time steps. A minor time step is a subdivision of the major time step. The solver produces a result at each major time step and uses results at minor time steps to improve the accuracy of the result at the major time step. For continuous solvers, the output of the Lookup Table Dynamic block can appear like a stair step because the signal is fixed in minor time step to avoid incorrect results. For more information about the effect of solvers on block output, see “Solvers” in the Simulink documentation.

## Data Type Support

The Lookup Table Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Main tab” on page 1-965
- “Signal Attributes tab” on page 1-965

### Main tab

#### Lookup Method

Specify the lookup method. For details, see “How the Block Generates Output” on page 1-963.

### Signal Attributes tab

#### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt('double')`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

#### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Examples

For an example of...	See...
Breakpoint and table data entry	“Entering Data Using Inports of the Lookup Table Dynamic Block”

## Magnitude-Angle to Complex

Convert magnitude and/or a phase angle signal to complex signal

### Library

Math Operations

### Description

#### Supported Operations

The Magnitude-Angle to Complex block converts magnitude and phase angle inputs to a complex output. The angle input must be in radians.

The block supports the following combinations of input dimensions when there are two block inputs:

- Two inputs of equal dimensions
- One scalar input and the other an n-dimensional array

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

#### Effect of Out-of-Range Input on CORDIC Approximations

If you use the CORDIC approximation method (see “Definitions” on page 1-969), the block input for phase angle has the following restrictions:

- For signed fixed-point types, the input angle must fall within the range  $[-2\pi, 2\pi]$  radians.
- For unsigned fixed-point types, the input angle must fall within the range  $[0, 2\pi]$  radians.

The following table summarizes what happens for an out-of-range input:

Block Usage	Effect of Out-of-Range Input
Simulation	An error appears.
Generated code	Undefined behavior occurs.
Accelerator modes	

Ensure that you use an in-range input for the Magnitude-Angle to Complex block when you use the CORDIC approximation. Avoid relying on undefined behavior for generated code or Accelerator modes.

## Definitions

### CORDIC

CORDIC is an acronym for COordinate Rotation DIgital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

### Data Type Support

The block accepts real input signals of the following data types:

- Floating point

- Fixed point (only when **Approximation method** is CORDIC)

The following restrictions also apply:

- If one input uses a floating-point type, the other input must use the same data type. For example, both signals must be **double** or **single**.
- If one input uses a fixed-point type, the other input must also use a fixed-point type.

## Parameters

### Input

Specify the kind of input: a magnitude input, an angle input, or both.

#### Angle (Magnitude)

Input	What to Specify
Magnitude	The constant phase angle of the output signal in radians
Angle	The constant magnitude of the output signal

This parameter is not available when **Input** is Magnitude and angle.

### Approximation method

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines:

- For signed fixed-point types, the input angle must fall within the range  $[-2\pi, 2\pi]$  radians.
- For unsigned fixed-point types, the input angle must fall within the range  $[0, 2\pi]$  radians.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	None or CORDIC	Same as input
Signed, fixed point	CORDIC	fixdt(1, $WL + 2$ , $FL$ ) where $WL$ and $FL$ are the word length and fraction length of the magnitude
Unsigned, fixed point	CORDIC	fixdt(1, $WL + 3$ , $FL$ ) where $WL$ and $FL$ are the word length and fraction length of the magnitude

### Number of iterations

Specify the number of iterations to perform the CORDIC algorithm. The default value is 11.

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Entering a value that is not a positive integer causes an error.

This parameter is available when you set **Approximation method** to CORDIC.

### Scale output by reciprocal of gain factor

Select this check box to scale the real and imaginary parts of the complex output by a factor of  $(1/\text{CORDIC gain})$ . This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output,  $X + iY$ . However, scaling the output adds two extra multiplication operations, one for  $X$  and one for  $Y$ .

This parameter is available when you set **Approximation method** to CORDIC.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Characteristics

Data Types	Double   Single   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# Manual Switch

Switch between two inputs

## Library

Signal Routing

## Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. The block propagates the selected input to the output, while the block discards the unselected input. You can interactively control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

## Data Type Support

The Manual Switch block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Allow the two inputs to differ in size” on page 1-975
- “Sample time” on page 1-255

## Allow the two inputs to differ in size

Select this check box to allow input signals with different sizes.

### Settings

**Default:** Off

On

Block allows input signals with different sizes, and propagates the input signal size to the output signal.

Off

Block expands scalar inputs to have the same dimensions as nonscalar inputs. For more information, see “Scalar Expansion of Inputs and Parameters”.

### Command-Line Information

**Parameter:** varsize

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'off'

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

The following models show how to use the Manual Switch block:

- sldemo\_auto\_climatecontrol
- sldemo\_fuelsys
- sldemo\_doublebounce

## Characteristics

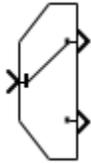

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

## Manual Variant Sink

Switch amongst multiple variant choices at output

### Library

Signal Routing

### Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

It can have two or more output ports and has one input port. Each output port is associated with a variant control.

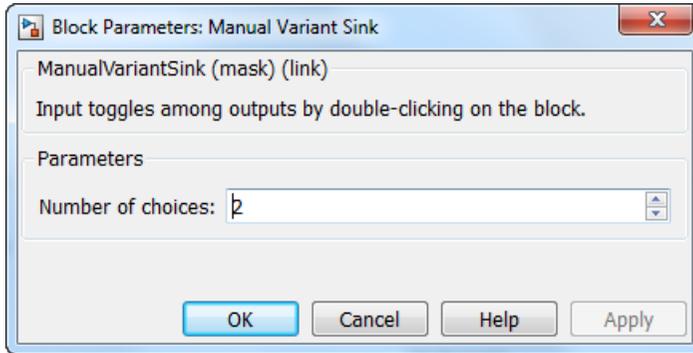

To toggle between the variant choices at output, double-click the block. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

### Data Type Support

The Manual Variant Sink block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Dialog Box and Parameters

To open the block dialog box, right-click the block and select **Mask > Mask Parameters**.

By default, the number of output choice is 2. You can change the number of outputs by typing a value in the **Number of choices** box. The maximum number of output choices can be 25.

---

**Note:** Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.

---

### Command-Line Information

Parameter: NumChoices  
 Type: character vector  
 Value: 2–25  
 Default: 2

### Examples

To view how to use the Manual Variant Sink block, click Manual Variant Source and Sink Blocks.

### Characteristics

## Manual Variant Source

Switch amongst multiple variant choices at input

### Library

Signal Routing

### Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control.

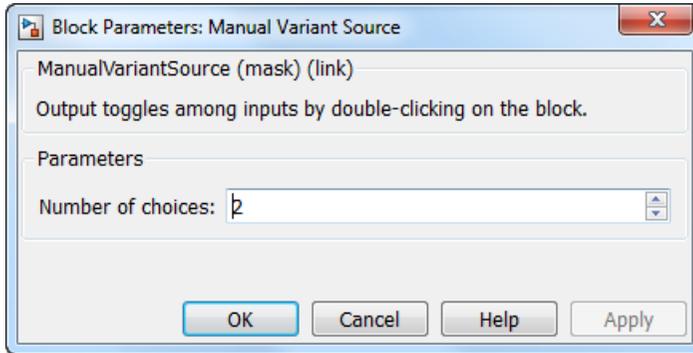

To toggle between the variant choices at input, double-click the block. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

### Data Type Support

The Manual Variant Source block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Dialog Box and Parameters

To open the block dialog box, right-click the block and select **Mask > Mask Parameters**.

By default, the number of input choices is 2. You can change the number of inputs by typing a value in the **Number of choices** box. The maximum number of input choices can be 25.

---

**Note:** Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the input choice.

---

### Command-Line Information

Parameter: NumChoices  
 Type: character vector  
 Value: 2–25  
 Default: 2

### Examples

To view how to use the Manual Variant Source block, click Manual Variant Source and Sink Blocks.

### Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

# Math Function

Perform mathematical function

## Library

Math Operations

## Description

The Math Function block performs numerous common mathematical functions.

---

**Tip:** To perform square root calculations, use the `Sqrt` block.

---

You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	$e^u$	exp
log	Natural logarithm	$\ln u$	log
10^u	Power of base 10	$10^u$	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$ u ^2$	(abs(u)).^2 (see abs and power)
square	Power 2	$u^2$	u.^2 (see power)

Function	Description	Mathematical Expression	MATLAB Equivalent
pow	Power	$u^v$	power
conj	Complex conjugate	$\bar{u}$	conj
reciprocal	Reciprocal	$1/u$	1./u (see rdivide)
hypot	Square root of sum squares	$(u^2+v^2)^{0.5}$	hypot
rem	Remainder after division	—	rem
mod	Modulus after division	—	mod
transpose	Transpose	$u^T$	u.' (see “Array vs. Matrix Operations” (MATLAB))
hermitian	Complex conjugate transpose	$u^H$	u' (see “Array vs. Matrix Operations” (MATLAB))

The block output is the result of the operation of the function on the input or inputs. The functions support the following types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
exp	yes	yes	—
log	yes	yes	—
10^u	yes	yes	—
log10	yes	yes	—
magnitude^2	yes	yes	—
square	yes	yes	—
pow	yes	yes	—
conj	yes	yes	—
reciprocal	yes	yes	—

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
hypot	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
rem	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
mod	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
transpose	yes	—	yes
hermitian	yes	—	yes

The name of the function appears on the block. The appropriate number of input ports appears automatically.

**Tip:** Use the Math Function block instead of the Fcn block when you want vector or matrix output, because the Fcn block produces only scalar output.

## Data Type Support

The following table shows the input data types that each function of the block can support.

Function	single	double	boolean	built-in integer	fixed point
exp	yes	yes	—	—	—
log	yes	yes	—	—	—
10 <sup>u</sup>	yes	yes	—	—	—

Function	single	double	boolean	built-in integer	fixed point
log10	yes	yes	—	—	—
magnitude^2	yes	yes	—	yes	yes
square	yes	yes	—	yes	yes
pow	yes	yes	—	—	—
conj	yes	yes	—	yes	yes
reciprocal	yes	yes	—	yes	yes
hypot	yes	yes	—	—	—
rem	yes	yes	—	yes	—
mod	yes	yes	—	yes	—
transpose	yes	yes	yes	yes	yes
hermitian	yes	yes	—	yes	yes

All supported modes accept both real and complex inputs, except for **reciprocal**, which does not accept complex fixed-point inputs.

The block output is real or complex, depending on what you select for **Output signal type**.

## Parameters

### Function

Specify the mathematical function. See Description for more information about the options for this parameter.

### Output signal type

Specify the output signal type of the Math Function block as **auto**, **real**, or **complex**.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
exp, log, 10u, log10, square, pow, reciprocal,	real	real	real	complex
	complex	complex	error	complex

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
conjugate, transpose, hermitian				
magnitude squared	real	real	real	complex
	complex	real	real	complex
hypot, rem, mod	real	real	real	complex
	complex	error	error	error

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

---

**Note** Some parameters on this pane are available only when the function you select in the **Function** parameter supports fixed-point data types.

---

### Output minimum

Specify the minimum value that the block can output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Output maximum

Specify the maximum value that the block can output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in Simulink User's Guide for more information.

#### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

#### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

#### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	<p>The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127.</p> <p>Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code>, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code>, is -126.</p>

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Direct Feedthrough	Yes
Sample Time	Inherited from driving block
Scalar Expansion	Yes, of the input when the function requires two inputs
Dimensionalized	Yes
Multidimensionalized	Yes, for all functions except <code>hermitian</code> and <code>transpose</code>
Zero-Crossing Detection	No

## MATLAB Function

Include MATLAB code in models that generate embeddable C code

## Library

User-Defined Functions

## Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function you create executes for simulation and generates code for a Simulink Coder target. If you are new to the Simulink and MATLAB products, see “What Is a MATLAB Function Block?” and “Create Model That Uses MATLAB Function Block” for an overview.

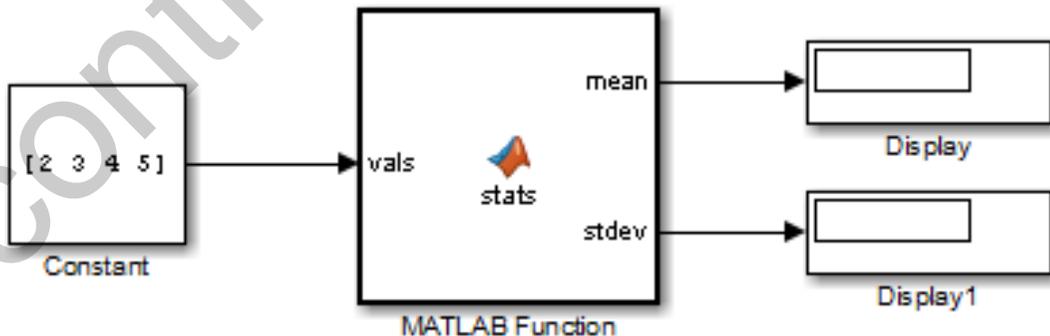

Double-clicking the MATLAB Function block opens its editor, where you write the MATLAB function, as in this example:

```

1  function [mean,stdev] = stats(vals)
2  % #codegen
3
4  % calculates a statistical mean and a standard
5  % deviation for the values in vals.
6
7  - len = length(vals);
8  - mean = avg(vals,len);
9  - stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
10 - coder.extrinsic('plot');
11 - plot(vals,'-+');
12 |
13 function mean = avg(array,size)
14 - mean = sum(array)/size;
    
```

To learn more about this editor, see “MATLAB Function Block Editor”.

You specify input and output data to the MATLAB Function block in the function header as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the model:

You can also define data, input triggers, and function call outputs using the Ports and Data Manager, which you access from the MATLAB Function Block Editor by selecting **Edit Data**. See “Ports and Data Manager”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.

See “Best Practices for Defining Variables for C/C++ Code Generation”.

- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. A list of supported functions is given in “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List”. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations” (MATLAB).
- Matrix operations like `size`, and `length`
- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

See “Functions and Objects Supported for C/C++ Code Generation — Category List” for a complete list of function categories.

---

**Note** Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few `eps` initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

---

**Note:** In the MATLAB Function block, the `%#codegen` directive is included to emphasize that the block’s MATLAB algorithm is always intended for code generation. The

`%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the MATLAB Function block. For more information see “Compilation Directive  `%#codegen`”.

---

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Extrinsic Functions” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the Ports and Data Manager, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Type Function Arguments”, “Size Function Arguments”, and “Add Parameter Arguments” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

## Data Type Support

The MATLAB Function block accepts inputs of any type that Simulink supports, including fixed-point and enumerated types. For more information, see “Data Types Supported by Simulink”.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

## Parameters

See the reference page for the **Subsystem**, **Atomic Subsystem**, **Nonvirtual Subsystem**, **CodeReuse Subsystem** blocks for information about each block parameter.

## Examples

The following models shows how to use the MATLAB Function block:

- sldemo\_radar\_eml
- sldemo\_eml\_galaxy

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes (default). To disable, in the Ports and Data Manager, clear the <b>Allow direct feedthrough</b> check box.
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced in R2011a**

# MATLAB System

Include System object in model

## Library

User-Defined Functions

## Description

The MATLAB System block brings existing System objects (based on matlab.System) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB® code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations” (MATLAB), like plus, minus, and power
- Matrix operations, like size and length
- Advanced matrix operations, like lu, inv, svd, and chol
- Trigonometric functions, like sin, cos, sinh, and cosh

## System Objects

To use the MATLAB System block, you must first have a new System object™ or use an existing one. For more information, see “System Object Integration”.

## Data Type Support

The MATLAB System block accepts inputs of most types that Simulink supports. It does not support virtual buses as input or output. It does not support nonvirtual buses that contain variable-size signals. For more information, see “Data Types Supported by Simulink”.

For information on fixed-point support for this block, see “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

## Parameters

### System object name

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

### Settings

**Default:** None

### Tips

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### New

Click this button to create a System object from a template.

Select one of these options.

- **Basic**

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

- **Advanced**

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

- **Simulink Extension**

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

### Settings

**Default:** Basic

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Simulate using

Select the simulation mode.

## Settings

### Default: Code generation

#### Code generation

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is **Code generation**, system objects accept a maximum of 32 inputs.

#### Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Dependency

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

#### Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Dependency

This check box appears when you use the showFiSettingsImpl method in the System object.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### Treat these inherited Simulink signal types as fi objects

Specify which inherited data types to treat as fi data types.

### Settings

**Default:** Fixed-point

Fixed-point

Treat fixed-point data types as fi data types.

## Fixed-point & Integer

Treat fixed-point and integer data types as fi data types.

### Dependency

This check box appears when you use the showFiSettingsImpl method in the System object.

## MATLAB System fimath

Specify which fixed-point math settings to use.

### Settings

**Default: Same as MATLAB**

#### Fixed-point

Use the current MATLAB fixed-point math settings.

#### Specify Other

Enable the edit box for specifying the desired fixed-point math settings. For information on setting fixed-point math, see `fimath`.

### Dependency

This check box appears when you use the showFiSettingsImpl method in the System object.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Code Generation	Yes
-----------------	-----

# Memory

Output input from previous time step

## Library

Discrete

## Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds and delays all elements of the vector by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

---

**Tip:** Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver `ode15s` or `ode113`.
  - The input to the block changes during simulation.
- 

When the Memory block inherits a discrete sample time, the block is analogous to the **Unit Delay** block. However, the Memory block does not support state logging. If logging the final state is necessary, use a **Unit Delay** block instead.

## Comparison with Similar Blocks

### Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

### Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_enginewc (Compression subsystem)</li> </ul>
Memory on page 1-1003	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> <li>• sldemo_bounce</li> <li>• sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)</li> </ul>
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_radar_em1</li> <li>• aero_dap3dof</li> </ul>

### Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	Yes	No, because the block can only inherit	Yes

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
		sample time (from the driving block or the solver used for the entire model).	
Support for frame-based signals	Yes	No	Yes
Support for state logging	Yes	No	No

## Data Type Support

The Memory block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type. Simulink does not allow the initial output of this block to be `inf` or `NaN`.

### Inherit sample time

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this checkbox has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: [0, 1].
- If the solver is a fixed-step solver, the [0, 1] sample time converts to the solver step size after sample-time propagation.

### Direct feedthrough of input during linearization

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering, use the following commands.

First compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

Next, terminate the compilation with the following command.

```
model([],[],[],'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

### Treat as a unit delay when linearizing with discrete sample time

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

### State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### **State name must resolve to Simulink signal object**

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### **Signal object class**

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select **Customize class lists**. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Outport Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### **Code generation storage class**

Select state storage class for code generation.

#### **Default: Auto**

#### **Auto**

**Auto** is the appropriate storage class for states that you do not need to interface to external code.

#### **StorageClass**

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

**State name** enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

### TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

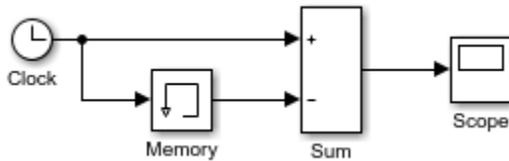

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

See “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation for more information.

## Examples of Memory Block Usage

### Usage with the Clock Block

The following model shows how to display the step size in a simulation. The Sum block subtracts the time at the previous step, which the Memory block generates, from the current time, which the Clock block generates.

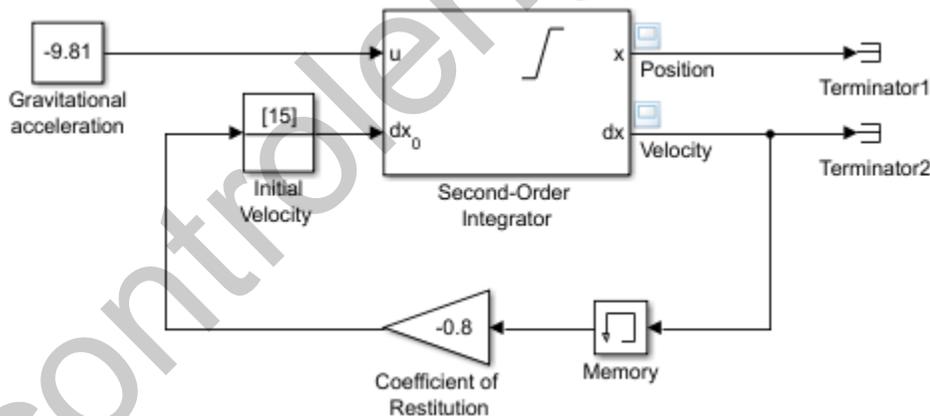

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a fixed-step solver. Therefore, the sample time of the Memory block is the solver step size, or 1.

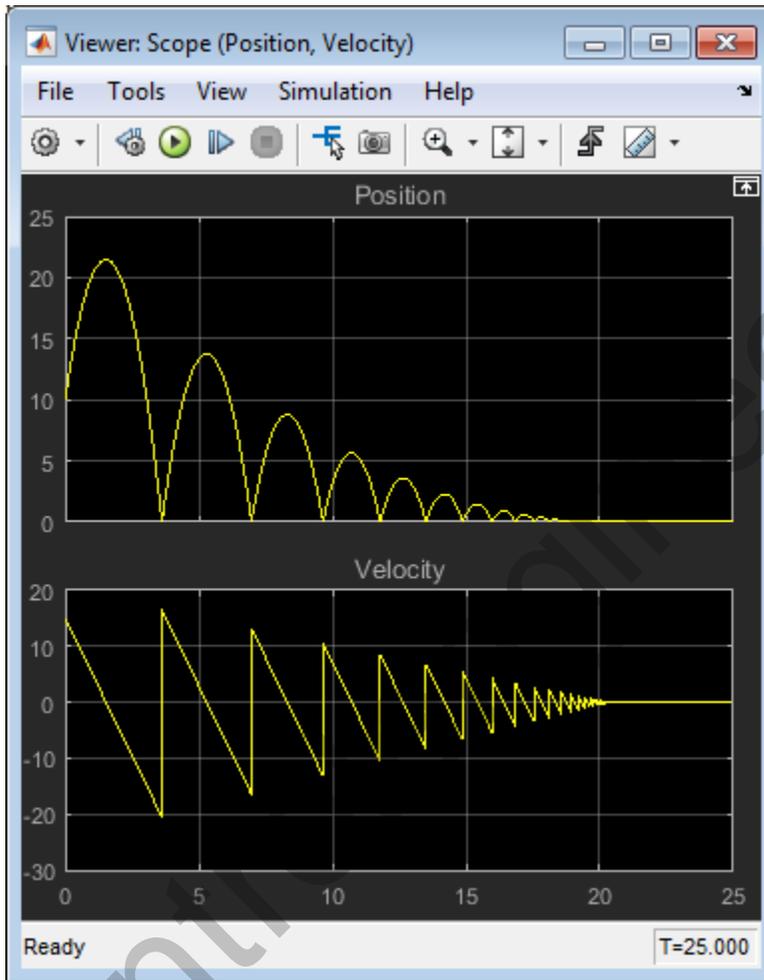

If you replace the Memory block with a Unit Delay block, you get the same results. The Unit Delay block inherits a discrete sample time of 1.

## Usage with the Second-Order Integrator Block

The `sldemo_bounce` model shows how a bouncing ball reacts after being tossed into the air. The  $dx$  port of the Second-Order Integrator block and the Memory block capture the velocity of the ball just before it hits the ground.

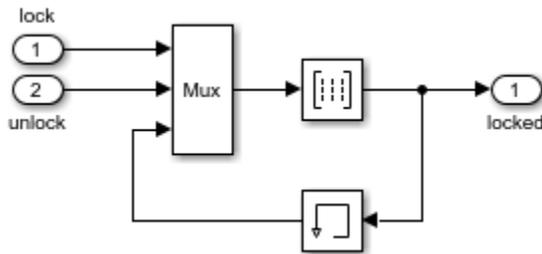

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (`ode23`) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step:  $[0, 1]$ . When you run the model, you get the following results:

If you replace the Memory block with a Unit Delay block, you get the same results. However, a warning also appears due to the discrete Unit Delay block inheriting a continuous sample time.

## Usage with the Combinatorial Logic Block

The `sldemo_clutch` model shows how you can use the Memory block with the Combinatorial Logic block to implement a finite-state machine. This construct appears in the Friction Mode Logic/Lockup FSM subsystem.

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (`ode23`) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step:  $[0, 1]$ .

## Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Depends on the type of solver used. If you select the <b>Inherit sample time</b> check box, the block inherits sample time from the driving block.
Direct Feedthrough	No, except when you select <b>Direct feedthrough of input during linearization</b>
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

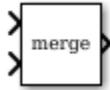

## See Also

Unit Delay, Zero-Order Hold

Introduced before R2006a

## Merge

Combine multiple signals into single signal

## Library

Signal Routing

## Description

The Merge block combines its inputs into a single output line whose value at any time is equal to the most recently computed output of its driving blocks. You can specify any number of inputs by setting the block's **Number of inputs** parameter.

Use Merge blocks only to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

Merge blocks assume that all driving signals share the same signal memory. The shared signal memory should be accessed only in mutually exclusive fashion. Therefore, always use alternately executing subsystems to drive Merge blocks.

All signals that connect to a Merge block, or exist anywhere in a network of Merge blocks, are functionally the same signal, and are therefore subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.

## Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

- Always use conditionally-executed subsystems to drive Merge blocks.

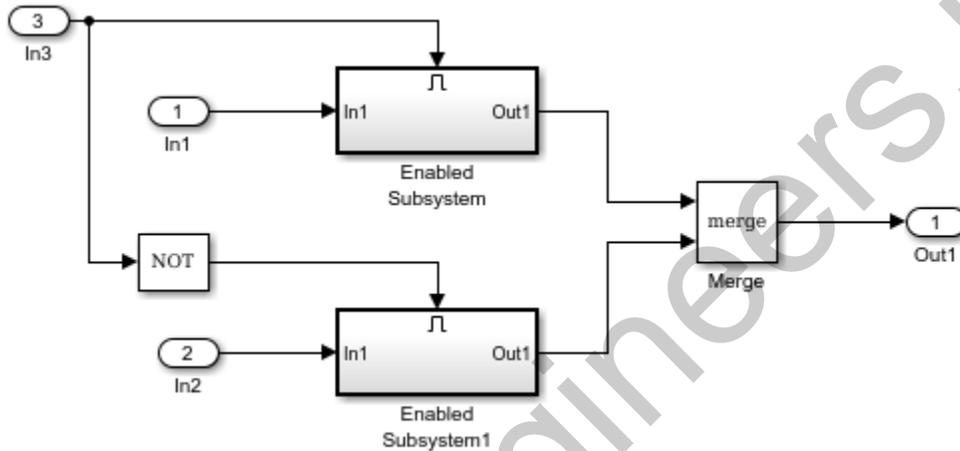

- Write your control logic to ensure that at most one of the driving conditionally-executed subsystems executes at any time step.
- Do not connect more than one input of a Merge block to the same conditionally-executed subsystem.
- Always connect a Merge block to at least two input signals.
- Ensure that all input signals have the same sample time.
- Always set the **Initial output** parameter of the Merge block, unless the output port of the Merge block connects to another Merge block.
- Do not branch a signal that inputs to a Merge block, if you use the default setting of **Classic** for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter. See the last example in “Merge Block Usage” on page 1-1014 for additional usage guidelines relating to branched signals.
- For all conditionally-executed subsystem **Output** blocks that drive Merge blocks, set the **Output when disabled** parameter to **held**.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.
- In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.
  - The source of the constant value is a grounded signal.
  - The source of the constant value is a constant block with a non-tunable parameter.
    - There is only one constant block that feeds the Merge block.
    - All other input signals to the Merge block are from conditionally executed subsystems.
    - The Merge block and output blocks of all conditionally executed subsystems should not specify any initial outputs.

## Merge Block Usage

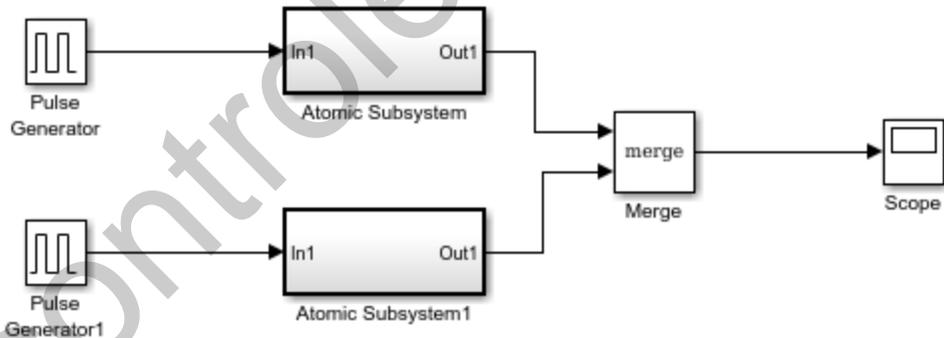

For each input of a Merge block, the topmost non-atomic and nonvirtual source must be a conditionally-executed subsystem that is not an Iterator Subsystem.

You can use the Model Advisor to check Merge block usage in your model. For more information, see “Check usage of Merge blocks” on page 8-40.

The following schematic shows valid Merge block usage, merging signals from two conditionally-executed subsystems.

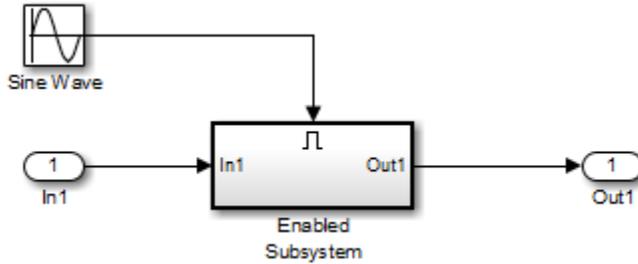

The following example is also a valid Merge block usage, where the topmost nonatomic, nonvirtual source is a conditionally executed subsystem.

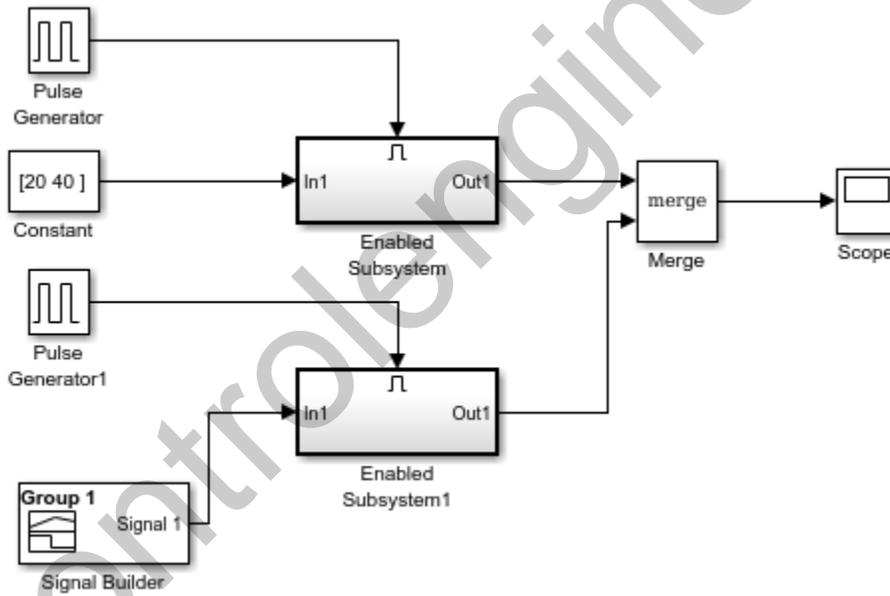

Each Atomic Subsystem block contains an enabled subsystem.

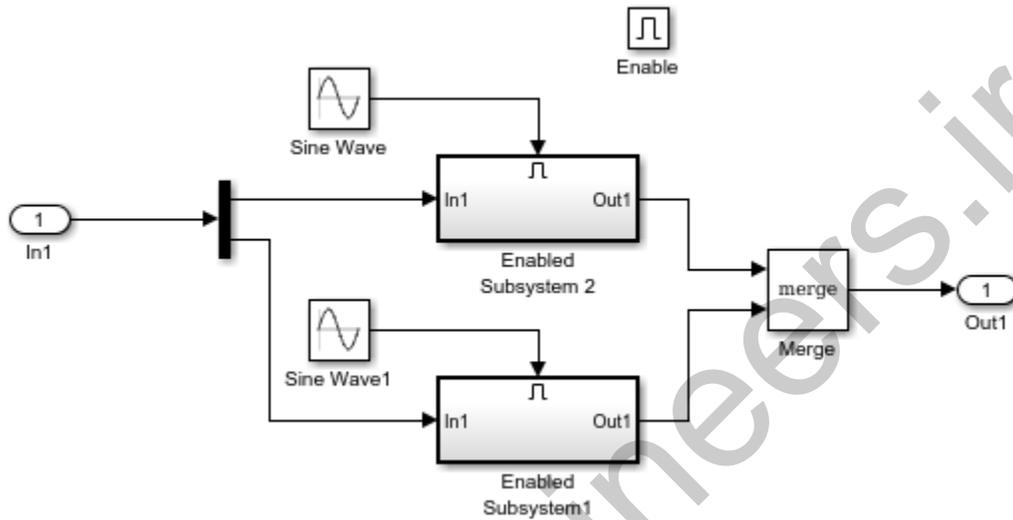

# 1 Blocks – Alphabetical List

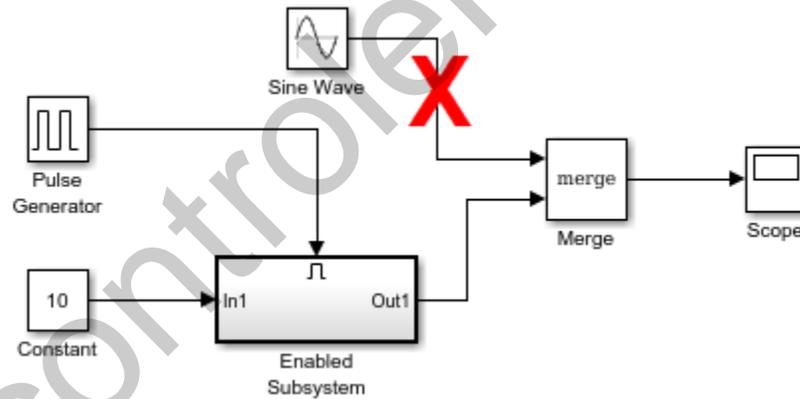

You can also use multiple Merge blocks at different levels of the model hierarchy. The following example contains a Merge block at the model root.

A Merge block is also located inside the Enabled Subsystem block, one level down.

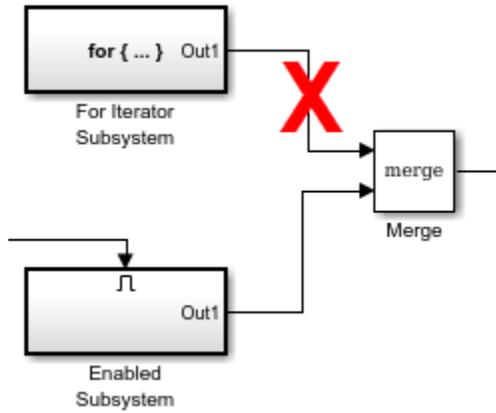

A Merge block *cannot* connect to a Sine Wave block because a Sine Wave block is not a conditionally-executed subsystem.

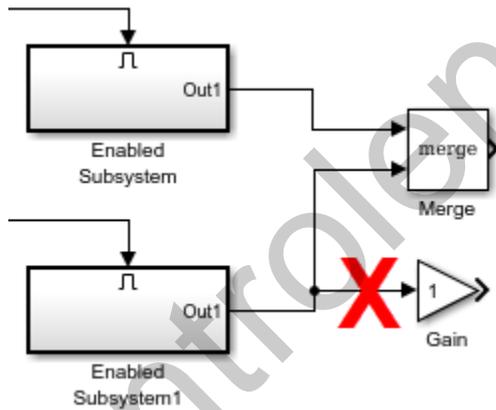

A Merge block *cannot* connect to a For Iterator Subsystem.

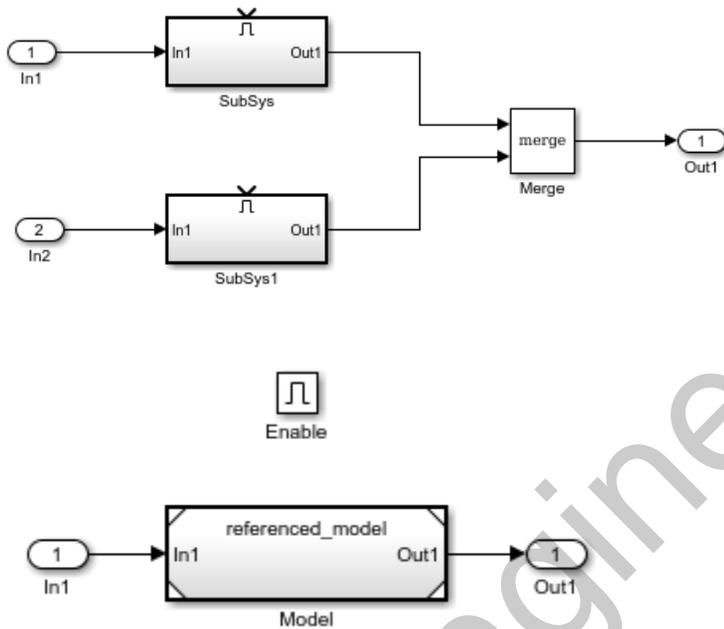

1 Blocks – Alphabetical List

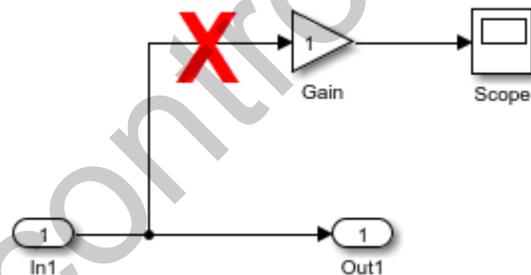

A Merge block *cannot* connect to a branched signal.

In the following model, the referenced model has a signal that branches. The subsystem **Subsys1** includes a Model block that references `referenced_model`. It includes a block that inputs to a block in the referenced model and also inputs to the Merge block that is outside of the referenced model.

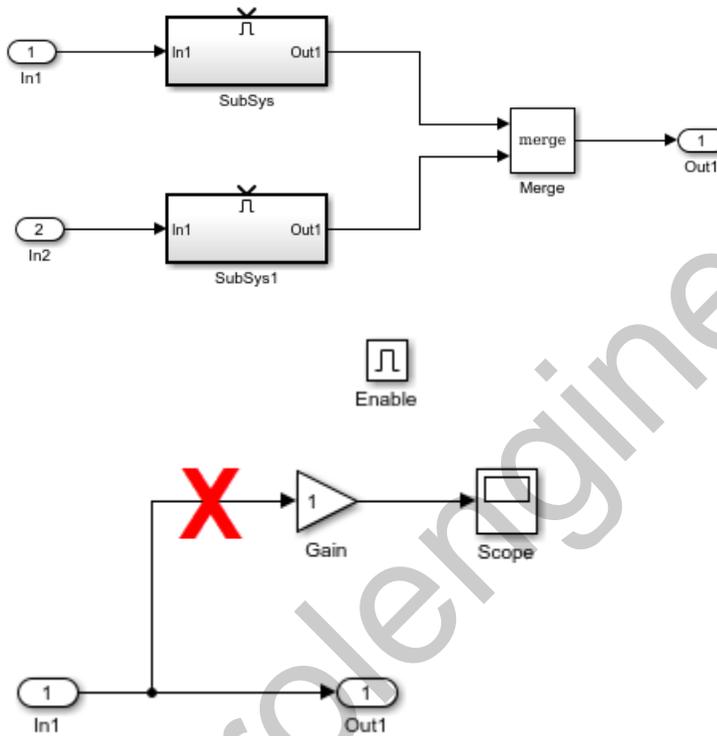

The referenced model includes a signal that incorrectly branches to a Gain block and to the Out1 Outputport block, which connects to the Merge block that is outside of the referenced model.

The following example also shows a branched signal in a subsystem that connects to a Merge block, which is *not allowed* if you use the default setting of **Classic** for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter.

If you set the **Underspecified initialization detection** parameter to **Simplified**, then the following example does *not* generate an error. For more information on simplified initialization mode, see “Underspecified initialization detection”.

### Initial Output Value

You can specify an initial output value for the Merge block by setting the **Initial output** parameter.

If you do not specify an initial output value, the block’s initial output depends on the initialization mode and the driving blocks. In Simplified initialization mode, for an unspecified (empty matrix [ ]) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see “Initializing Signal Values”. In Classic initialization mode, for an unspecified (empty matrix [ ]) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering

for these sources may vary, initialization may be inconsistent for the simulation and the code generation of a model. For example, the following model can produce inconsistent initialization:

- The model contains a Merge block with two inputs: one driven by a Stateflow chart and the other driven by a conditionally executed subsystem (such as an Enabled Subsystem).
- The Merge block **Initial output** parameter is unspecified (that is, specified as empty matrix ([ ])) and the model uses Classic initialization mode.
- The Stateflow chart initializes the output being merged to `val1`.
- The conditionally executed subsystem initializes the output being merged to different value `val2`.
- Both the Stateflow chart and the conditionally executed subsystem do not execute at the first time step.

Because the initialization ordering may vary, the output of the Merge block at the first time step is `val1` if the Stateflow chart initializes last and `val2` if the conditionally executed subsystem initializes last. The initialization ordering is different for simulation and code generation.

To address this issue, use one of the following approaches:

- Set the **Initial output** parameter of the Merge block, unless the output port of the Merge block connects to another Merge block.
- Turn on simplified initialization mode, set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**.

To use the **Simplified** initialization setting, specify the **Initial output** value for all *root* Merge blocks. A root Merge block is any Merge block with an output port that does not connect to another Merge block.

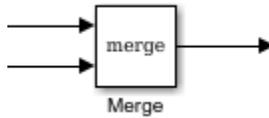

To upgrade your model to simplified initialization mode, use the Model Advisor check “Check usage of Merge blocks” on page 8-40.

For more information on simplified initialization mode, see “Underspecified initialization detection”.

### Single-Input Merge

Single-input merge is not supported. Each Merge block must have at least two inputs.

Use Merge blocks only for signals that require merging. If you were previously connecting a Merge block input to a Mux block, use a multi-input Merge block instead.

### Input Dimensions and Merge Offsets

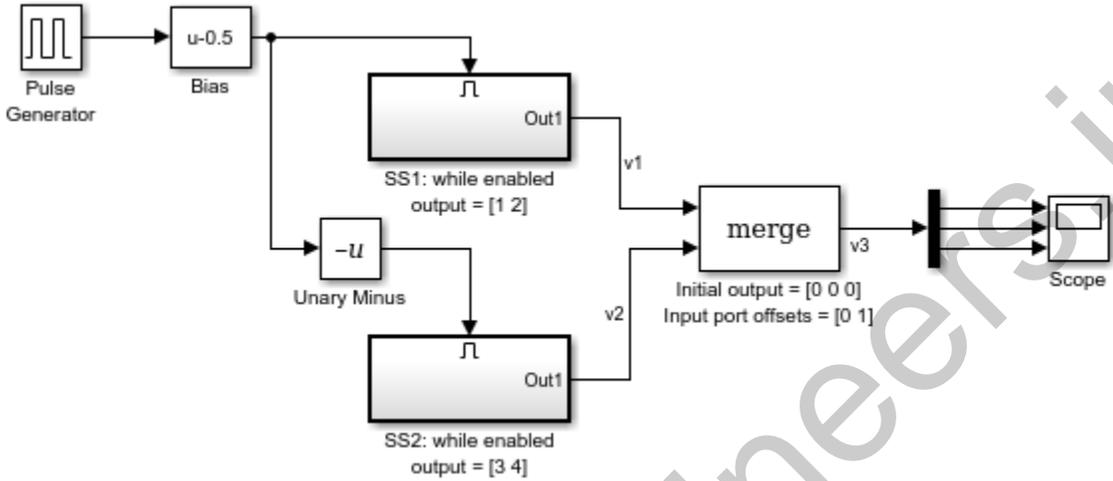

The Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs, unless you select the **Allow unequal port widths** parameter.

If you select **Allow unequal port widths**, the block accepts scalars and vectors (but not matrices) having differing numbers of elements. Further, the block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$$\max(w_1+o_1, w_2+o_2, \dots, w_n+o_n)$$

where  $w_1, \dots, w_n$  are the widths of the input signals and  $o_1, \dots, o_n$  are the offsets for the input signals.

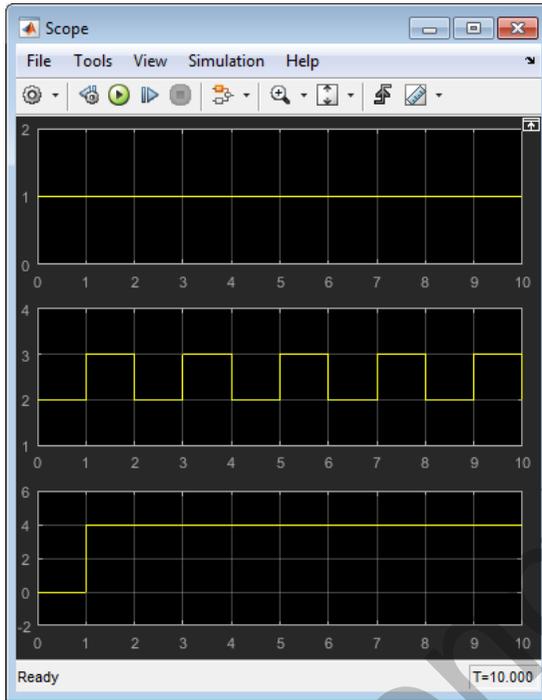

Suppose that you have the following block diagram:

The Merge block has the following output width:

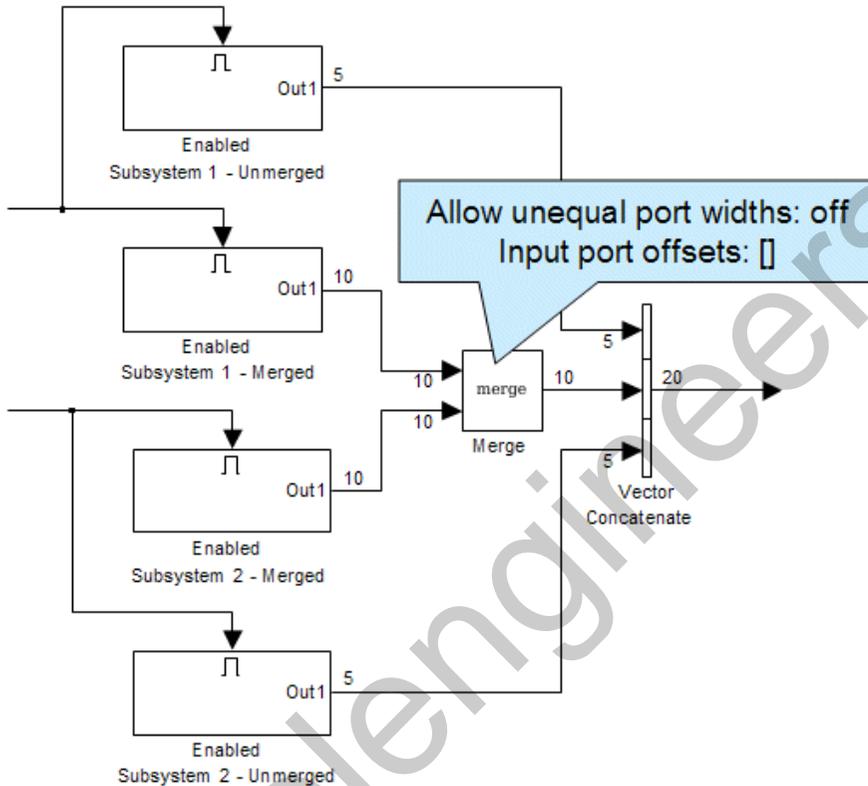

$$\max(2+0, 2+1)=3$$

In this example, the offset of v1 is 0 and the offset of v2 is 1. The Merge block maps the elements of v1 to the first two elements of v3 and the elements of v2 to the last two elements of v3. Only the second element of v3 is effectively merged, as shown in the scope output:

If you use Simplified Initialization Mode, you must clear the **Allow unequal port widths** check box. The input port offsets for all input signals must be zero.

Consider using Merge blocks only for signal elements that require true merging. Other elements can be combined with merged elements using the Concatenate block, as shown in the following example.

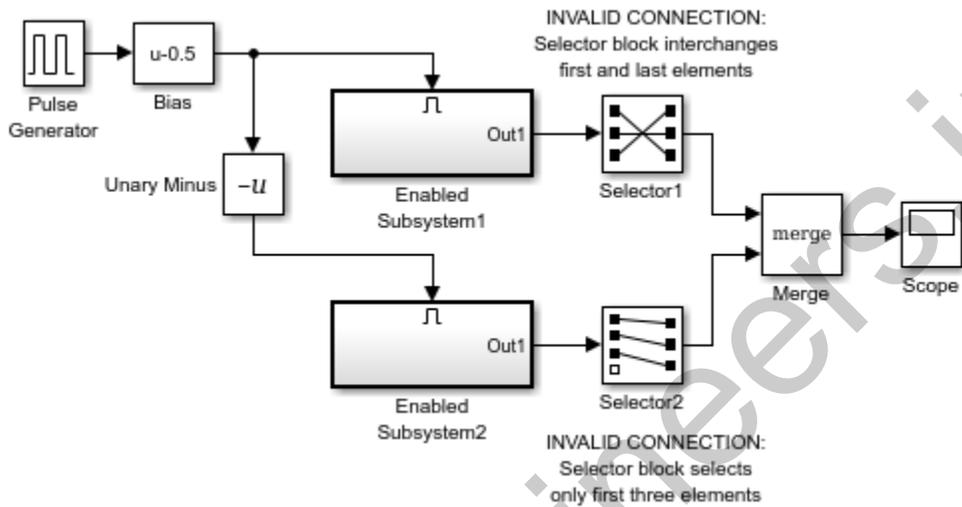

For more information on simplified initialization mode, see “Underspecified initialization detection”.

### Combining or Reordering of Input Signals

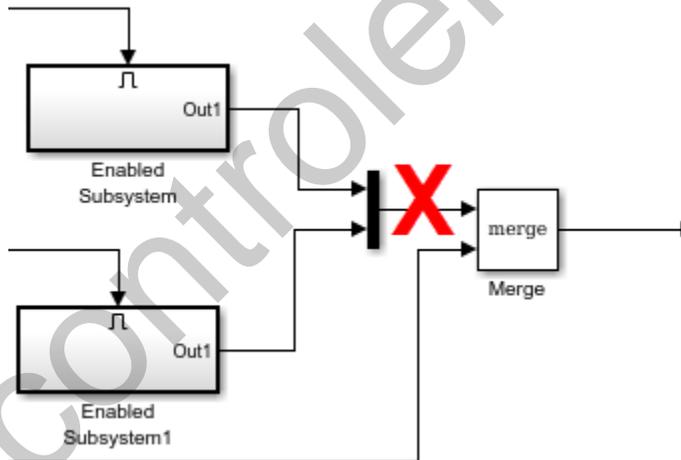

A Merge block does not accept input signals whose elements have been reordered or partially selected. In addition, you should not connect input signals to the Merge block that have been combined outside of a conditionally-executed subsystem.

For example, in the following block diagram, the Merge block does not accept the output of the first Selector block because the Selector block interchanges the first and last elements of the vector signal. Similarly, the Merge block does not accept the output of the second Selector block because the Selector block selects only the first three elements.

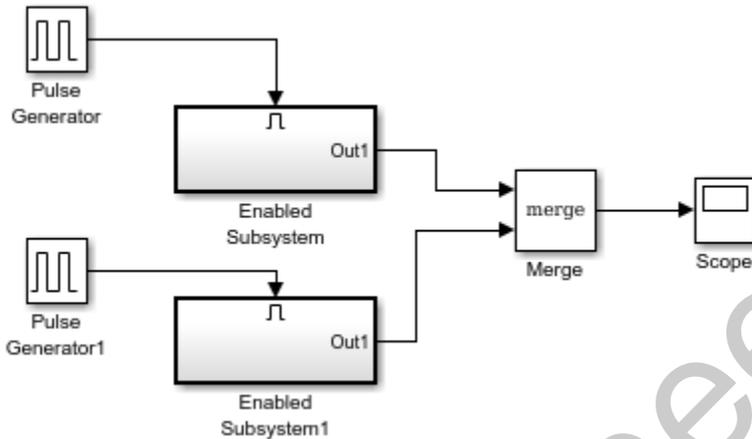

1 Blocks – Alphabetical List

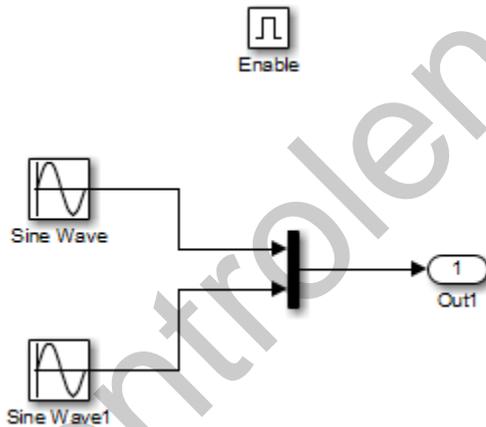

If you use simplified initialization mode, the following arrangement is *not allowed* because two signals are being combined outside of a conditionally-executed subsystem.

You can, however, combine or reorder Merge block input signals within a conditionally-executed subsystem. For example, the following model is valid.

Each Enabled Subsystem contains the following blocks.

For more information on simplified initialization mode, see “Underspecified initialization detection”.

### Conditionally-Executed Subsystem Output Reset

The Outports of conditionally-executed subsystems being merged should not reset when disabled. This action can cause multiple subsystems to update the Merge block at the

same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the Merge block by computing its output.

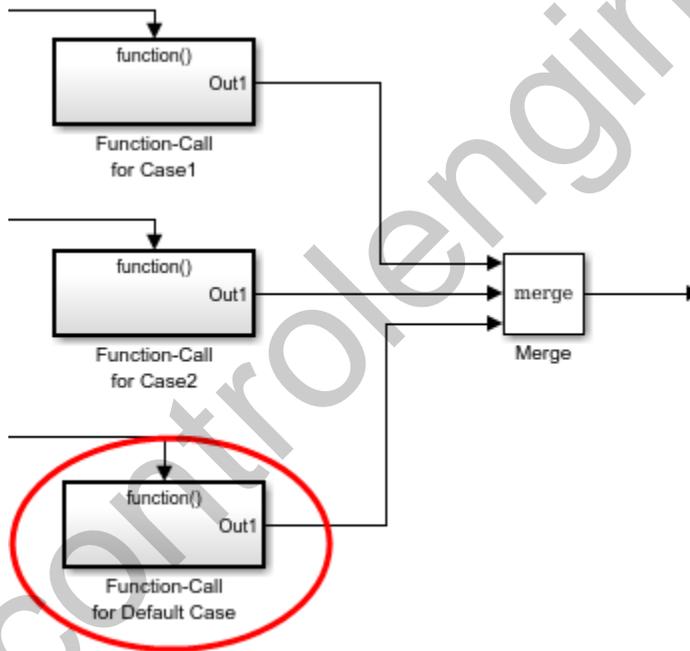

To prevent this behavior, set the Output block parameter **Output when disabled** to held for each conditionally-executed subsystem being merged.

---

**Note:** If you are using Simplified Initialization Mode, you *must* set the Output block parameter **Output when disabled** to held.

---

Instead of resetting the subsystem output when it is disabled, add an additional subsystem for the default case, and use control logic to run this subsystem if nothing else runs. For example, see the following block layout:

For more information on simplified initialization mode, see “Underspecified initialization detection”.

## Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the S-Function block's output is reusable. Simulink software displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts` for more information.

## Data Type Support

The Merge block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. All inputs must be of the same data type and numeric type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of inputs

Specify the number of input ports to merge.

### Initial output

Specify the initial value of output For more information, see .

### Allow unequal port widths

Select this check box to allow the block to accept inputs having different numbers of elements.

### Input port offsets

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

## Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- **Allow unequal port widths** must be disabled.
- All inputs to the merge must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Merge block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Composite Signals” and **Bus-Capable Blocks** for more information.

You can use an array of buses as an input signal to a Merge block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. Using an array of buses with a Merge block involves these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Number of inputs** — Set to a value of 2 or greater.
- **Initial condition** — You can specify this parameter with:
  - The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
  - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
  - A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## MinMax

Output minimum or maximum input value

### Library

Math Operations

### Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You can choose the function to apply by selecting one of the choices from the **Function** parameter list.

If the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.

If the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

The MinMax block ignores any input value that is NaN, except when every input value is NaN. When all input values are NaN, the output is NaN, either as a scalar or the value of each output vector element.

### Data Type Support

The MinMax block accepts and outputs real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Function

Specify whether to apply the function `min` or `max` to the input.

### Number of input ports

Specify the number of inputs to the block.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

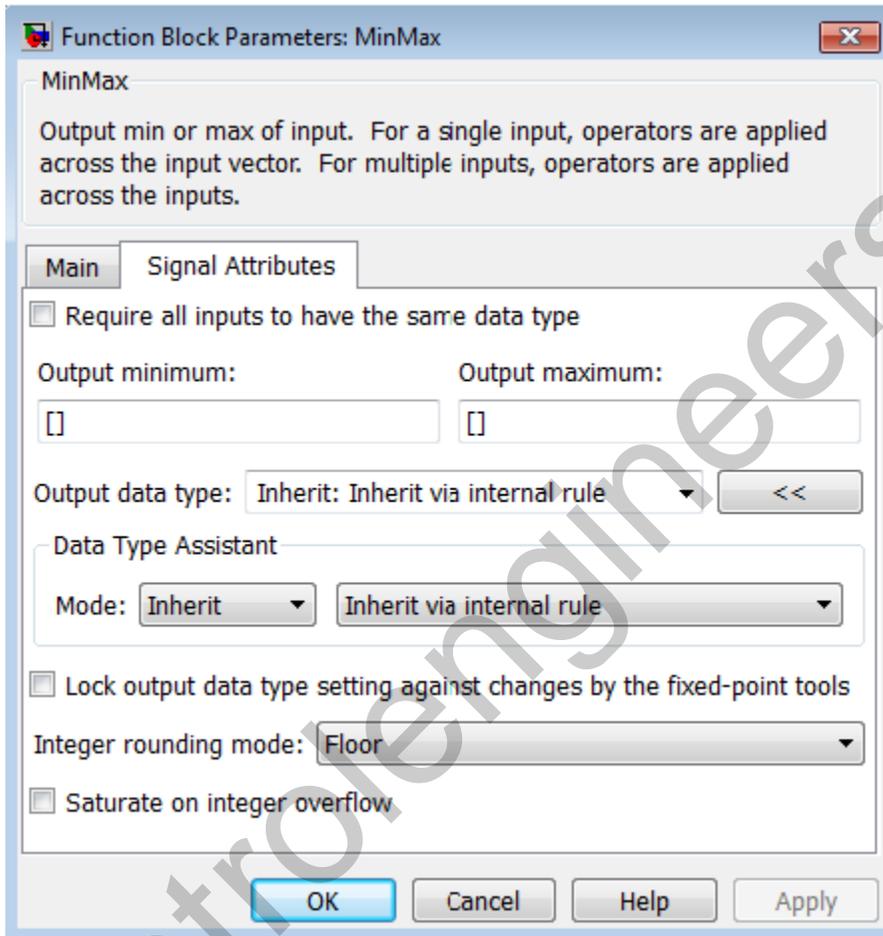

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

The **Signal Attributes** pane of the MinMax block dialog box appears as follows:

### Require all inputs to have the same data type

Select this check box to require that all inputs have the same data type.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

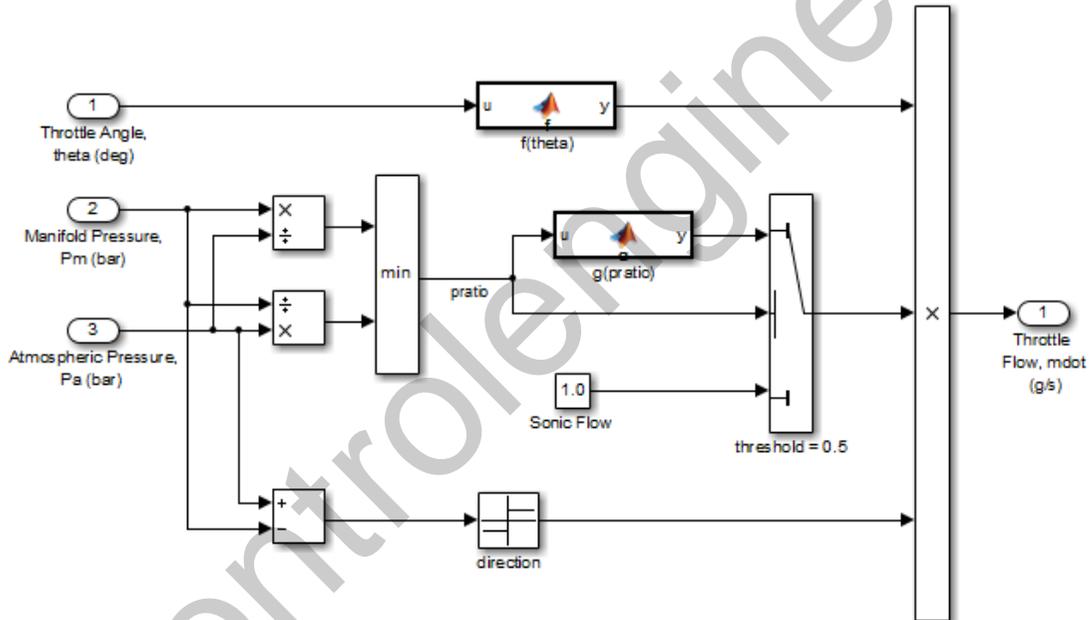

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can

detect when overflow is not possible. In this case, the code generator does not produce saturation code.

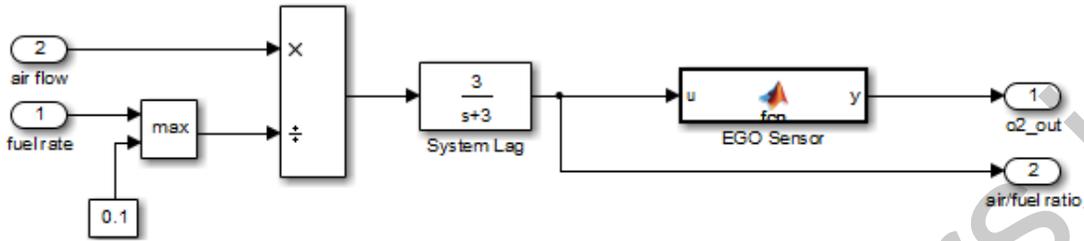

## Examples

The `sldemo_fuelsys` model shows how to use the MinMax block.

In the Engine Gas Dynamics/Throttle & Manifold/Throttle subsystem, the MinMax block uses the `min` operator:

In the Engine Gas Dynamics/Mixing & Combustion subsystem, the MinMax block uses the `max` operator:

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

MinMax Running Resettable

Introduced before R2006a

# MinMax Running Resettable

Determine minimum or maximum of signal over time

## Library

Math Operations

## Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs  $u$ . You specify whether the block outputs the minimum or the maximum with the **Function** parameter.

The block can reset its state based on an external reset signal  $R$ . When the reset signal  $R$  is TRUE, the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. If you specify a scalar **Initial condition** parameter, the block expands the parameter to have the same dimensions as a nonscalar input. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

## Data Type Support

The MinMax Running Resettable block accepts and outputs real signals of any numeric data type that Simulink supports, except `boolean`. The MinMax Running Resettable block supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Function

Specify whether the block outputs the minimum or the maximum.

### Initial condition

Specify initial condition.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

## Model, Model Variants

Include multiple model implementations as block in another model

### Library

Ports & Subsystems

### Description

The Model block allows you to include a model as a block in another model. The included model is called a *referenced model*, and the model containing it (via the Model block) is called the *parent model*.

The Model block displays input ports and output ports corresponding to the top-level input and output ports of the referenced model. Using these ports allow you to connect the referenced model to other blocks in the parent model. See “Model Referencing” for more information.

A Model block can specify the referenced model:

- Statically, as a Model block parameter value, which must name the model literally
- Dynamically, depending on base workspace values

A Model Variants block is a Model block with variants enabled. The Model block parameter dialog box contains the **Enable Variants** button by default. If you click the **Enable Variants** button, the Model Variants block parameter dialog opens. The Model Variants block parameter dialog contains the **Disable Variants** button by default. Therefore, you can use either the Model block or the Model Variants block for implementing model variants. For more information about how to specify a referenced model for multiple specifications, see “Set up Model Variants”.

By default, the contents of a referenced model are user-visible, but you can hide the contents as described in “Protected Model”.

A signal that connects to a Model block is functionally the same signal outside and inside the block. A given signal can have at most one associated signal object, so the signal connected to the Model block cannot have a signal object in both the parent and the referenced models. For more information, see `Simulink.Signal`.

The Model block supports signal label propagation. For details specific to model referencing and model variants, see:

- “Processing for Referenced Models”
- “Processing for Variants and Configurable Subsystems”

An `InitFcn` callback in a top model cannot change parameters used by referenced models.

## Data Type Support

Determined by the root-level inputs and outputs of the model referenced by the Model block.

## Parameters

- “Code interface” on page 1-1044
- “Enable variants” on page 1-1045
- “Variant choices” on page 1-1046
- “Variant control” on page 1-1048
- “Condition (read only)” on page 1-1049
- “Model name” on page 1-1050
- “Model arguments (for this instance)” on page 1-1051
- “Model arguments” on page 1-1052
- “Model argument values (for this instance)” on page 1-1053
- “Simulation mode” on page 1-1054
- “Override variant conditions and use following variant” on page 1-1056

- “Variant” on page 1-1057
- “Variant control” on page 1-1058
- “Generate preprocessor conditionals” on page 1-1059
- “Disable variants” on page 1-1059

Controlengineers.ir

## Code interface

Specify whether the generated code is from top model or referenced model.

### Settings

**Default:** Model reference

#### Model reference

Code generated from referenced model as part of a model reference hierarchy. Code generation uses the `slbuild('model', 'ModelReferenceRTWTarget')` command.

#### Top model

Code generated from top model with the standalone code interface. Code generation uses the `slbuild('model')` command.

### Dependency

Setting the **Simulation mode** parameter to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)** enables this parameter.

### Command-Line Information

**Parameter:** CodeInterface

**Type:** character vector

**Value:** 'Model reference' | 'Top model'

**Default:** 'Model reference'

### See Also

- “Software-in-the-Loop Simulation” (Embedded Coder)
- “Processor-in-the-Loop Simulation” (Embedded Coder)
- `slbuild`

## Enable variants

Enables variants and opens the Model Variants block parameter dialog box, which is hidden by default. The Model Variants block parameter dialog is the default block parameter dialog for the Model Variants block.

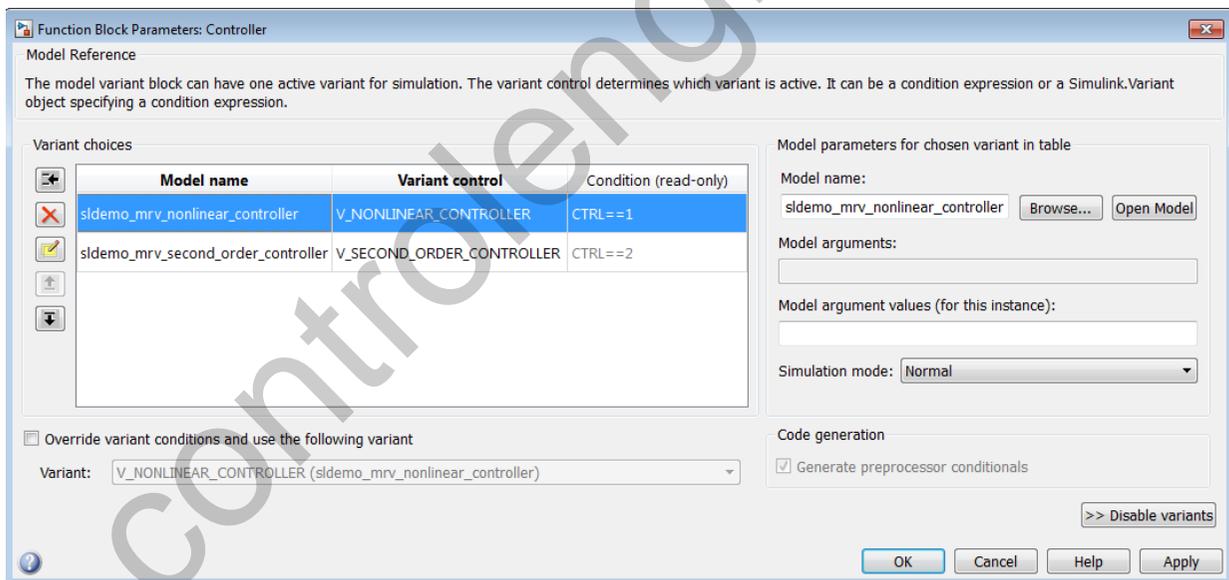

### Settings

**Default:** Disabled

### Dependencies

This button enables the Model Variants Sections, which include: **Variant choices** table, **Model parameters for the chosen variant in table** section, parameters to override variants, and a **Code generation** section.

The following example shows the Model variants options from the example model sldemo\_mdhref\_variants.

### See Also

“Set up Model Variants”

## Variant choices

Displays a table of variant choices, associated model names, variant controls, and conditions. The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** The table has a row for each variant object in the base workspace. The **Variant choices** table includes the **Model name**, its associated **Variant control**, and **Condition (read-only)** columns.

Use the **Add a new variant** button to add a new row to the table. See the description of the **Model name**, **Variant control**, and **Condition (read-only)** table columns for information about how to set values for table rows.

### Tips

You can use buttons to the left of the **Variant choices** table to modify the table.

Function	Button
<b>Add a new variant:</b> Add a new, empty row below the currently selected row	
<b>Delete selected variant:</b> Delete the currently selected row. (Models and objects are not affected.)	
<b>Create/Edit selected variant object:</b> Creates a <code>Simulink.Variant</code> object in the base workspace and opens the <code>Simulink.Variant</code> object parameter dialog in order to specify the variant <b>Condition</b> . This button will only be enabled for valid <code>Simulink.Variant</code> objects.	
<b>Move variant up:</b> Move the currently selected row up one slot in the table	
<b>Move variant down:</b> Move the currently selected row down one slot in the table	

### Dependency

**Enable variants** enables this parameter.

## Command-Line Information

**Parameter:** Variants

**Type:** array

**Value:** array of variant structures where each element specifies one variant. The structure fields are:

- `variant.Name` (character vector) — The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.
- `variant.ModelName` (character vector) — The name of the referenced model associated with the specified variant control in the Model block.
- `variant.ParameterArgumentNames` (character vector) — Read-only character vector containing the names of the model arguments for which the Model block must supply values.
- `variant.ParameterArgumentValues` (character vector) — The values to supply for the model arguments when this variant is the active variant.
- `variant.SimulationMode` (character vector) — The execution mode to use when this variant is the active variant.
  - Possible values are 'Accelerator' | 'Normal' | 'Software-in-the-loop (SIL)' | 'Processor-in-the-loop (PIL)'

## See Also

“Configure the Model Variants Block”

## Variant control

Displays the variant controls in the base workspace. The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** `Variant1`

To enter a variant control name, double-click **Variant control** column in a new row and enter the variant control expression.

### Dependency

**Enable variants** enables this parameter.

### Command-Line Information

**Structure field:** Represented by the `variant.Name` field in the `Variants` parameter structure

**Type:** character vector

**Value:** Variant control associated with the variant.

**Default:** ''

### See Also

- `Simulink.Variant`

## Condition (read only)

Display the condition for the `Simulink.Variant` object.

### Settings

This read-only field displays the condition for the associated model variant in the base workspace. Click the **Edit selected variant object** button to specify the condition for the selected variant object.

### Tips

The variant condition must be a Boolean expression that references at least one base workspace variable or parameter. For example, `FUEL == 2 && EMIS == 1`. Do not surround the condition with parentheses or single quotes. The expression can include:

- MATLAB variables defined in the base workspace
- Simulink parameter objects defined in the base workspace
- Scalar variables
- Enumerated values
- Operators `==`, `~=`, `&&`, `||`, `~`
- Parentheses for grouping

### Dependency

**Enable variants** enables this parameter.

### See Also

“Configure the Model Variants Block”

## Model name

Display or enter the name of the model associated with the variant control in the **Variant choices** table.

### Settings

**Default:** ''

The name must be a valid MATLAB identifier.

The extension, for example, `.slx`, is optional.

### Tips

You can type the model name into the table, or you can use the **Model parameters for chosen variant in table** controls to find and open models.

- To navigate to the model that you want to reference for the selected variant in the table, click **Browse**.
- To confirm your selection, click **Open Model**.

### Dependency

**Enable variants** enables this parameter.

### Command-Line Information

**Structure field:** represented by the `variant.ModelName` field in the `Variants` parameter structure

**Type:** character vector

**Value:** any valid value

**Default:** name of the referenced model exactly as you typed it, with any surrounding white space removed. When you set the model name programmatically or using the dialog box, Simulink automatically sets the values of `ModelName` and `ModelFile` based on the value of `ModelNameDialog`.

### See Also

“Set up Model Variants”

## Model arguments (for this instance)

Display and specify model arguments for the target referenced model. To specify a value for each argument, use the right column in the table.

Model arguments enable each instance of the referenced model to use a different value for a block parameter.

### Settings

**Default:** ''

To configure model arguments in a referenced model and to specify argument values in a Model block, see “Parameterize Instances of a Reusable Referenced Model”.

### Dependency

**Enable variants** disables this parameter.

### Command-Line Information

**Parameter:** ParameterArgumentValues (corresponding to the **Value** column in the table)

**Type:** structure

**Value:** Structure with one field for each model argument that the referenced model defines

**Default:** Structure with no fields

### See Also

“Parameterize Instances of a Reusable Referenced Model”

## Model arguments

Display model arguments for the variant control highlighted in the **Variant choices** table.

Declaring a variable to be a model argument allows each instance of the model to use a different value for that variable.

### Settings

**Default:** ''

This is a read-only parameter that displays model arguments for the variant control highlighted in the **Variant choices** table. To create model arguments, refer to “Model Arguments for Model Variants Blocks”.

### Dependency

**Enable variants** enables this parameter.

### Command-Line Information

**Structure field:** Represented by the `variant.ParameterArgumentNames` field in the Variants parameter structure `OneArgName`

**Type:** character vector

**Value:** Enter model arguments as a comma separated list

**Default:** ''

### See Also

- “Model Arguments for Model Variants Blocks”
- “Set up Model Variants”

## Model argument values (for this instance)

Specify values to be passed as model arguments for the model variant control highlighted in the **Variants choices** table, each time the simulation invokes the model.

### Settings

Enter the values in this parameter as a list in the same order as the corresponding argument names in the **Model arguments** field. To separate the items in the list, use commas, spaces, or semicolons.

### Dependency

**Enable variants** enables this parameter.

### Command-Line Information

**Structure field:** Represented by the `variant.ParameterArgumentValues` field in the `Variants` parameter structure `OneArgName`

**Type:** character vector

**Value:** Any valid value

**Default:** ''

### See Also

- “Model Arguments for Model Variants Blocks”
- “Set up Model Variants”

## Simulation mode

Set the simulation mode for the model variant control highlighted in the **Variants choices** table. This setting specifies whether to simulate the model by generating and executing code or by interpreting the model in Simulink.

### Settings

#### Default: Accelerator

##### Accelerator

Creates a MEX-file for the sub model and then executes the sub model by running the S-function.

##### Normal

Executes the sub model interpretively, as if the sub model were an atomic subsystem implemented directly within the parent model.

##### Software-in-the-loop (SIL)

This option requires the Embedded Coder software. Generates production code using model reference target for the sub model. This code is compiled for, and executed on, the host platform.

##### Processor-in-the-loop (PIL)

This option requires the Embedded Coder software. Generate production code using model reference target for the sub model. This code is compiled for, and executed on, the target platform. A documented target connectivity API supports exchange of data between the host and target at each time step during the PIL simulation.

### Dependency

**Enable variants** enables this parameter.

### Command-Line Information

**Structure field:** Represented by the `variant.SimulationMode` field in the `Variants` parameter structure

**Type:** character vector

**Value:** 'Accelerator' | 'Normal' | 'Software-in-the-loop (SIL)' | 'Processor-in-the-loop (PIL)'

**Default:** 'Accelerator'

### See Also

- “Specify Different Value for Each Instance of Reusable Model”

Controlengineers.ir

## Override variant conditions and use following variant

Specify whether to override the variant conditions and make the specified **Variant** parameter the active variant.

### Settings

**Default:** Off

On

Override the variant conditions and set the active variant to the value of the **Variant**

Off

Determine the active variant by the value of the variant conditions.

### Tip

Both this GUI parameter and the **Variant** GUI parameter (following) use the same API parameter, `OverrideUsingVariant`.

### Dependencies

**Enable variants** enables this parameter.

This parameter enables variants.

### Command-Line Information

**Parameter:** `OverrideUsingVariant`

**Type:** character vector

**Value:** '' if no overriding variant control is specified.

**Default:** ''

### See Also

“Create Variant Controls Programmatically”

## Variant

Specify the variant control associated with the model to use if you select **Override variant conditions and use the following variant**.

### Settings

**Default:** ''

Must be a valid non empty or non commented name.

### Tips

- You can use the **Variant** drop down to view a list of all variant controls currently available and their associated models.
- Both this GUI parameter and the **Override variant conditions and use following variant** GUI parameter (above) use the same API parameter, `OverrideUsingVariant`.

### Dependencies

**Enable variants** and **Override variant conditions and use the following variant** enable this parameter.

### Command-Line Information

**Parameter:** `OverrideUsingVariant`

**Type:** character vector (read-only)

**Value:** Variant control

### See Also

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

## Variant control

Enter the variant activation condition or the variant control that contains the expression for variant activation.

The variant control can be a boolean condition expression or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, define control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

### Dependency

Adding a Model block inside a Variant Subsystem block enables this parameter

### Command-Line Information

**Structure field:** Represented by the `variant.Name` field in the `Variants` parameter structure

**Type:** character vector

**Value:** Variant control associated with the variant

**Default:** ''

### See Also

- `Simulink.Variant`

## Generate preprocessor conditionals

When generating code for an ERT target, this parameter determines whether variant choices are enclosed within C preprocessor conditional statements (`#if`).

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

### Settings

**Default:** Disabled

### Dependencies

- The check box is available for generating only ERT targets.
- **Override variant conditions and use following variant** is cleared ('off')

### Command-Line Information

**Parameter:** GeneratePreprocessorConditionals

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

“Variant Systems” (Embedded Coder)

## Disable variants

Disable model reference variants and hide the Model Variants Section. The block retains any information you have entered and approved by clicking **Apply** or **OK**.

### Command-Line Information

**Parameter:** Variant

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Navigating a Model Block

- Double-clicking the prototype Model block in the **Ports & Subsystems** library opens its Block Parameters dialog box for inspection, but does not allow you to specify parameter values.
- Double-clicking an unresolved Model block opens its Block Parameters dialog box. You can resolve the block by specifying a **Model name**.
- Double-clicking a resolved Model block opens the model that the block references. You can also open the model by choosing **Open Model** from the **Context** or **Edit** menu.

To display the Block Parameters dialog box for a resolved Model block, choose **Model Reference Parameters** from the **Context** or **Edit** menu.

## Model Blocks and Direct Feed through

When a Model block is part of a cycle, and the block is a direct feed through block, an algebraic loop can result. An algebraic loop in a model is not necessarily an error, but it may not give the expected results. See:

- “Algebraic Loops” for information about direct feed through and algebraic loops.
- “Highlight Algebraic Loops in the Model” for information about seeing algebraic loops graphically.
- “Display Algebraic Loop Information” for information about tracing algebraic loops in the debugger.
- The “Model Configuration Parameters: Diagnostics” pane “Algebraic loop” option for information on detecting algebraic loops automatically.

## Direct Model Block Feed through Caused by Sub model Structure

A Model block may be a direct feed through block due to the structure of the referenced model. Where direct feed through results from sub model structure, and causes an unwanted algebraic loop, you can:

- Automatically eliminate the algebraic loop using techniques described in:
  - “Minimize algebraic loop”
  - “Minimize algebraic loop occurrences”
  - “Remove Algebraic Loops”

- Manually insert one or more Unit Delay blocks as needed to break the algebraic loop.

## Direct Model Block Feed through Caused by Model Configuration

Generic Real Time (grt) and Embedded Real Time (ert) based targets provide the option **Model Configuration Parameters > All Parameters > Single output/update function**. This option controls whether generated code has separate output and update functions, or a combined output/update function. See:

- “Entry-Point Functions and Scheduling” (Simulink Coder) for information about separate and combined output and update functions.
- “Single output/update function” (Simulink Coder) for information about specifying whether code has separate or combined functions.

When **Single output/update function** is enabled (default), a Model block has a combined output/update function. The function makes the block a direct feed through block for all inports, regardless of the structure of the referenced model. Where an unwanted algebraic loop results, you can:

- Disable **Single output/update function**. The code for the Model block then has separate output and update functions, eliminating the direct feed through and hence the algebraic loop.
- Automatically eliminate the algebraic loop using techniques described in:
  - “Minimize algebraic loop”
  - “Minimize algebraic loop occurrences”
  - “Remove Algebraic Loops”
- Manually insert one or more Unit Delay blocks as needed to break the algebraic loop.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Direct Feedthrough	If “Single output/update function” (Simulink Coder) is enabled (default), a Model block is a direct feed through block regardless of the structure of the referenced model.

	If “Single output/update function” (Simulink Coder) is disabled, a Model block may or may not be a direct feed through block, depending on the structure of the referenced model.
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

## Requirements, Limitations, and Tips for Model Variants

A Model Variants block and its referenced models must satisfy the requirements in “Simulink Model Referencing Requirements” and “Model Referencing Limitations”. You can nest Model Variants blocks to any level.

---

**Note:** For information on requirements and limitations that apply to *code generation* see “Represent Subsystem and Model Variants in Generated Code” (Embedded Coder).

---

### Tips

- A Model Variants block can log only those signals that the referenced model specifies as logged. If a model is a variant model, or contains a variant model, then you can either log all logged signals or log no logged signals. The Signal Logging Selector configuration for the model must be in one of these states:
  - The Logging Mode is set to Log all signals as specified in model.
  - The Logging Mode is set to **Override signals** and the check box for the model block is either checked () or empty (). The check box cannot be filled ().

For more information about logging referenced models, see “Models with Model Referencing: Overriding Signal Logging Settings”.

To enable logging programmatically, use the `DefaultDataLogging` parameter.

- You can enable or suppress warning messages about mismatches between a Model Variants block and its referenced model by setting diagnostics on the **Diagnostics Pane: Model Referencing**.

- During model compilation, Simulink evaluates variant objects before calling the `InitFcn` callback. Therefore, do not modify the condition of the variant object in the `InitFcn` callback.
- Each variant must have an associated variant control specified in the **Variant control** column. The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the variant controls as `Simulink.Parameter` objects.

## Model Info

Display model properties and text in model

## Library

Model-Wide Utilities

## Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

## Data Type Support

Not applicable.

## Parameters

### Specify Text and Properties to Display

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text Model Info.

- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

The block adds a token of the form `%<modelpropertyname>` to the edit box. In the text the block mask displays, Simulink will replace the token with the value of the property.

- 1 For example, if you select **Description** in the **Model properties** list and click the right arrow button, then the token

`%<Description>`

appears in the right edit box.

- 2 You could add some explanatory text before the model property, e.g. “Model description:”.
- 3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See “Version Information Properties” for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use Simulink Project. See “Source Control in Simulink Project”.

---

**Tip:** To add text, images, links, and equation annotations to a model, see instead “Describe Models Using Annotations”.

---

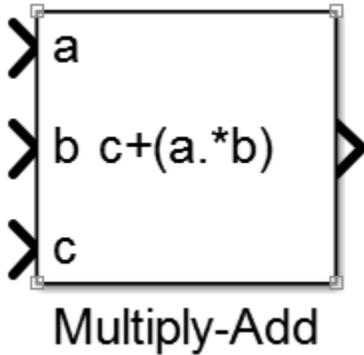

## Characteristics

Data Types	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

**Introduced before R2006a**

## Multiply-Add

Multiply-add combined operation

### Library

HDL Coder / HDL Operations

### Description

The Multiply-Add block computes the product of the first two inputs, a and b, and adds the result to the third input, c. The inputs can be vectors or scalars.

### Operation Precision

The multiplication operation is full precision, regardless of the output type. The **Integer rounding mode**, **Output data type**, and **Saturate on integer overflow** settings apply only to the addition operation.

### HDL Code Generation

Use the Multiply-Add block to map a combined multiply-add or a multiply-subtract operation to a DSP unit in your target hardware.

When you generate HDL code for your model, HDL Coder configures the multiply-add operation so that your synthesis tool can map to a DSP unit.

## Data Type Support

The Multiply-Add block accepts and outputs signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Function

Specify the function to perform a combined multiply and add or a multiply and subtract operation.

#### Settings

**Default:**  $c + (a \cdot b)$

You can set the function to:

- $c + (a \cdot b)$
- $c - (a \cdot b)$
- $(a \cdot b) - c$

### Output data type

Specify the output data type.

#### Settings

**Default:** Inherit: Inherit via internal rule

Set the output data type to:

- A rule that inherits a data type, for example, Inherit: Same as input

- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the Data Type Assistant dialog box, which helps you to set the **Output data type** parameter.

For more information, see “Control Signal Data Types” in Simulink User's Guide .

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Rounding” (Fixed-Point Designer).

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.

- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

#### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

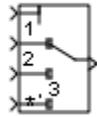

#### See Also

Introduced in R2015b

Controlengineers.ir

# Multiport Switch

Choose between multiple block inputs

## Library

Signal Routing

## Description

**Note:** A variant of the Multiport Switch block is the Index Vector block. For information on the Index Vector block, see “Multiport Switch Configured as an Index Vector Block” on page 1-1072.

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to select data input	Out-of-range condition
Integer value	None	Zero-based contiguous	Zero-based indexing	The control input is less than 0 or greater than

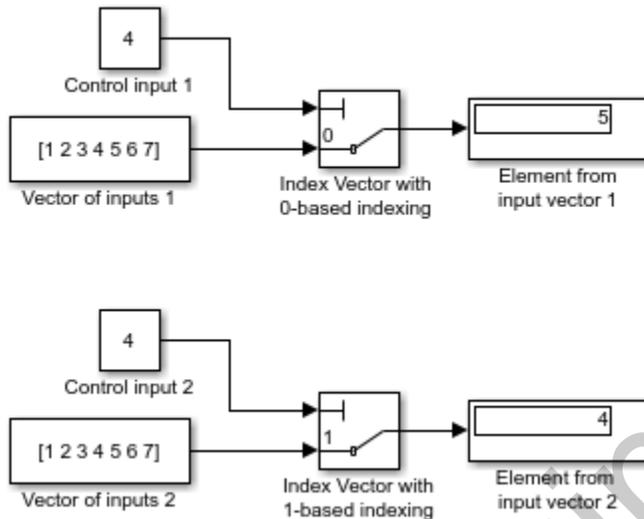

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to select data input	Out-of-range condition
				the number of data inputs minus one.
		One-based contiguous	One-based indexing	The control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The control input does not correspond to any specified data port index.
Not an integer value	The block truncates the value to an integer by rounding to zero.	Zero-based contiguous	Zero-based indexing	The truncated control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The truncated control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1073.

## Multiport Switch Configured as an Index Vector Block

An **Index Vector** is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

This model shows how the Index Vector works with zero-based and one-based indexing.

Index Vector is a block in the Simulink **Signal Routing** library. Alternatively, configure a Multiport Switch block to work as an Index Vector block by setting **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

## How the Block Handles an Out-of-Range Control Input

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

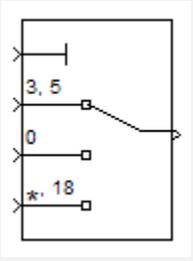

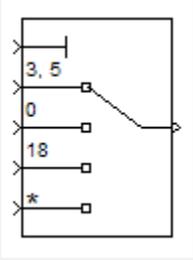

---

**Note:** If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

---

### Behavior for Simulation

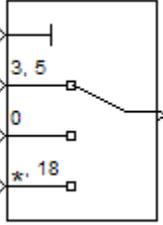

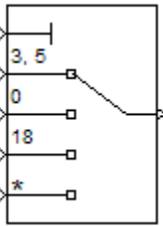

The following behavior applies only to simulation for your model.

Data port for default case	Diagnostic for default case		
	None	Warning	Error
Last data port 	Use the last data port and do not report any warning or error.	Use the last data port and report a warning.	Report an error and stop simulation.
Additional data port 	Use the additional data port with a * label and do not report any warning or error.	Use the additional data port with a * label and report a warning.	Report an error and stop simulation.

### Behavior for Code Generation

The following behavior applies to code generation for your model.

Data port for default case	Diagnostic for default case		
	None	Warning	Error
Last data port	Use the last data port.	Use the last data port.	Use the last data port.

Data port for default case	Diagnostic for default case		
	None	Warning	Error
			
Additional data port 	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

## Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes” on page 1-1092. For more information about variable-size signals, see “Variable-Size Signal Basics”.

## Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-1072.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

## Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	<ul style="list-style-type: none"> <li>• Set <b>Data port order</b> to <b>Specify indices</b>.</li> <li>• Set <b>Data port indices</b> to use this value for the last data port.</li> <li>• Set <b>Data port for default case</b> to <b>Last data port</b>.</li> </ul>	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	<ul style="list-style-type: none"> <li>• Set <b>Data port for default case</b> to <b>Additional data port</b>.</li> </ul>	This block configuration handles invalid values that the enumerated type does not explicitly represent.
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	<ul style="list-style-type: none"> <li>• Set <b>Data port for default case</b> to <b>Last data port</b>.</li> <li>• Set <b>Diagnostic for default case</b> to <b>None</b>.</li> </ul>	This block configuration avoids unnecessary diagnostic action.

Scenario	What to Do	Rationale
The block does not have a data input port for every value of the enumerated type.	<ul style="list-style-type: none"> <li>Set <b>Data port for default case</b> to <b>Additional data port</b>.</li> </ul>	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

## Data Type Support

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. If the control signal is numeric, it cannot be complex. If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port. If the underlying integer does not correspond to a data port, an error occurs.

The data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Data port order” on page 1-1079
- “Number of data ports” on page 1-1081
- “Data port indices” on page 1-1082
- “Data port for default case” on page 1-1084
- “Diagnostic for default case” on page 1-1085
- “Sample time” on page 1-255
- “Require all data port inputs to have the same data type” on page 1-1087
- “Lock output data type setting against changes by the fixed-point tools” on page 1-203
- “Integer rounding mode” on page 1-252
- “Saturate on integer overflow” on page 1-254
- “Allow different data input sizes” on page 1-1092

- “Output minimum” on page 1-1093
- “Output maximum” on page 1-1094
- “Output data type” on page 1-1095

- “Fraction length” on page 1-1103
- “Slope” on page 1-1104
- “Bias” on page 1-1105

Controlengineers.ir

## Data port order

Specify the type of ordering for your data input ports.

### Settings

**Default:** One-based contiguous (for Multiport Switch block), Zero-based contiguous (for Index Vector block)

#### Zero-based contiguous

Block uses zero-based indexing for ordering contiguous data ports.

#### One-based contiguous

Block uses one-based indexing for ordering contiguous data ports.

#### Specify indices

Block uses noncontiguous indexing for ordering data ports.

### Tips

- When the control port is of enumerated type, select **Specify indices**.
- If you select **Zero-based contiguous** or **One-based contiguous**, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs:

If the block has unused data ports and data port order is...	You get...
Zero-based contiguous or One-based contiguous	A warning
Specify indices	An error

### Dependencies

Selecting **Zero-based contiguous** or **One-based contiguous** enables the **Number of data ports** parameter.

Selecting `Specify indices` enables the **Data port indices** parameter.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

controlengineers.ir

## Number of data ports

Specify the number of data input ports to the block.

### Settings

**Default:** 3 (for Multiport Switch block), 1 (for Index Vector block)

The block icon changes to match the number of data input ports you specify.

### Dependency

Selecting **Zero-based contiguous** or **One-based contiguous** for **Data port order** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Data port indices

Specify an array of indices for your data ports.

### Settings

**Default:** {1,2,3}

The block icon changes to match the data port indices you specify.

### Tips

- To specify an array of indices that correspond to all values of an enumerated type, enter `enumeration('type_name')` for this parameter. Do not include braces.

For example, `enumeration('MyColors')` is a valid entry.

- To enter specific values of an enumerated type, use the `type_name.enumerated_name` format. Do not enter the underlying integer value.

For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.

- To indicate that more than one value maps to a data port, use brackets.

For example, the following entries are both valid:

- `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
- `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

### Dependency

Selecting `Specify indices` for **Data port order** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Data port for default case

Specify whether to use the last data port for out-of-range inputs, or to use an additional port.

### Settings

**Default:** Last data port

#### Last data port

Block uses the last data port for output when the control port value does not match any data port indices.

#### Additional data port

Block uses an additional data port for output when the control port value does not match any data port indices.

### Tip

If you set this parameter to **Additional data port** and **Number of data ports** is 3, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Diagnostic for default case

Specify the diagnostic action to take when the control port value does not match any data port indices.

### Settings

**Default:** Error

None

Simulink software takes no action.

Warning

Simulink software displays a warning and continues the simulation.

Error

Simulink software terminates the simulation and displays an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-1073.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Require all data port inputs to have the same data type

Specify allowed data types.

### Settings

**Default:** Off

On

Requires all data port inputs to have the same data type.

Off

Allows data port inputs to have different data types.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Allow different data input sizes

Select this check box to allow input signals with different sizes.

### Settings

**Default:** Off

On

Allows input signals with different sizes, and propagate the input signal size to the output signal.

Off

Requires that input signals be the same size.

### Command-Line Information

**Parameter:** AllowDiffInputSizes

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'off'

## Output minimum

Specify the minimum value that the block outputs.

### Settings

**Default:** [ ]

The default value is [ ] (unspecified).

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Tip

This number must be a finite real double scalar value.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Output maximum

Specify the maximum value the block outputs.

### Settings

**Default:** [ ]

The default value is [ ] (unspecified).

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Tip

This number must be a finite real double scalar value.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit:** Inherit via back propagation

Uses the data type of the driving block.

**double**

Specifies output data type **double**.

**single**

Specifies output data type **single**.

**int8**

Specifies output data type **int8**.

**uint8**

Specifies output data type **uint8**.

**int16**

Specifies output data type `int16`.

`uint16`

Specifies output data type `uint16`.

`int32`

Specifies output data type `int32`.

`uint32`

Specifies output data type `uint32`.

`fixdt(1,16,0)`

Specifies output data type fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Specifies output data type fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Uses a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables a list of possible values:

- Inherit via internal rule (default)
- Inherit via back propagation

##### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Specifies fixed-point data types.

##### Expression

Specifies expressions that evaluate to data types. Selecting **Expression** enables you to enter an expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

Signed

Specifies the fixed-point data as signed.

Unsigned

Specifies the fixed-point data as unsigned.

### Dependency

Selecting **Mode** > Fixed point enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependency

Selecting **Mode** > **Fixed point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependency

Selecting **Scaling** > **Binary point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependency

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependency

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Bus Support

The Multiport Switch block is a bus-capable block. The data inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- All the buses must be equivalent (same hierarchy with identical names and attributes for all elements).
- All signals in a nonvirtual bus input to a Multiport Switch block must have the same sample time. This requirement holds even when the elements of the associated bus object specify inherited sample times.

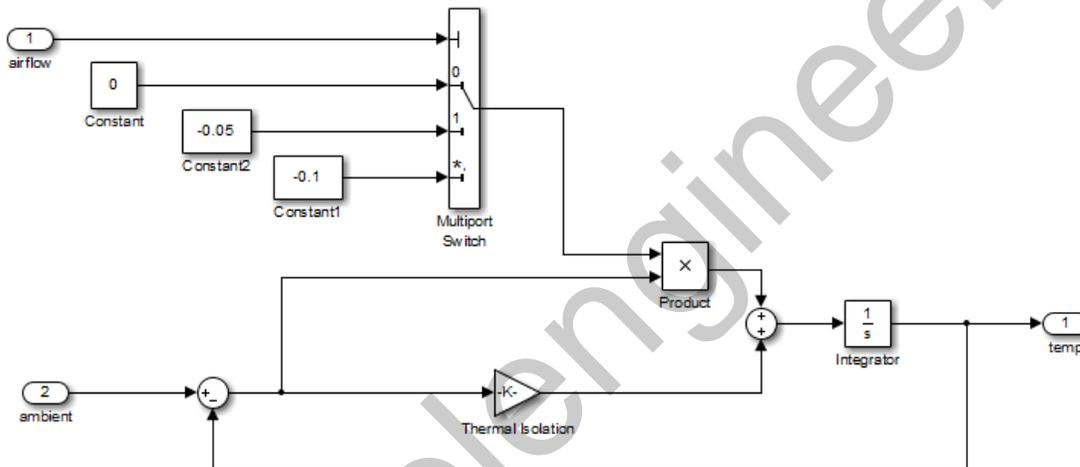

You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” for more information.

You can use an array of buses as an input signal to a Multiport Switch block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. When you use an array of buses with a Multiport Switch block, set **Number of data ports** to a value of 2 or greater.

## Examples

### Zero-Based Indexing for Data Ports

The `sf_aircontrol` model uses a Multiport Switch block in the Physical Plant subsystem. This block uses zero-based indexing for contiguous ordering of three data ports.

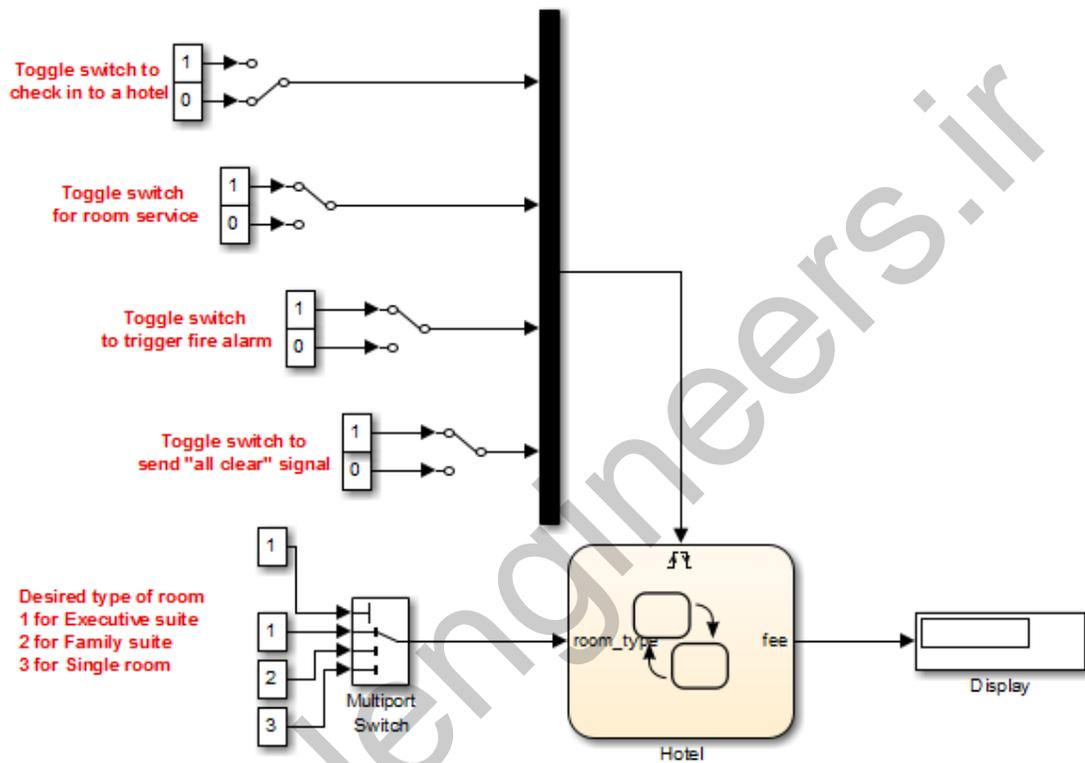

The indices are visible on the data port labels. You do not have to open the block dialog box to determine whether the data ports use zero-based or one-based indexing.

When you set **Data port for default case** to **Last data port**, the last data port includes a \* on the label. The comma after the \* indicates that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices 0, 1, or 2. In this case, the Multiport Switch block outputs a value of -0.1.

### One-Based Indexing for Data Ports

The `sf_semantics_hotel_checkin` model uses a Multiport Switch block. This block uses one-based indexing for contiguous ordering of three data ports.

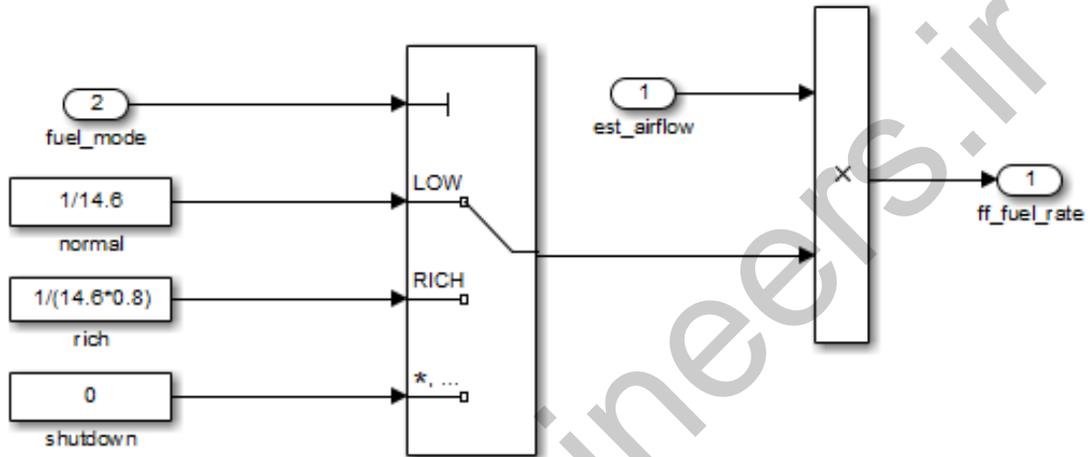

If you increase the size of the block icon, the indices are visible on the data port labels. You do not have to open the block dialog box to determine whether the data ports use zero-based or one-based indexing.

## Enumerated Names for Data Port Indices

The `sldemo_fuelsys` model uses a `Multiport Switch` block in the `fuel_rate_control1/fuel_calc/feedforward_fuel_rate` subsystem. This block uses the enumerated type `sld_FuelModes` to specify three data port indices: `LOW`, `RICH`, and `DISABLED`.

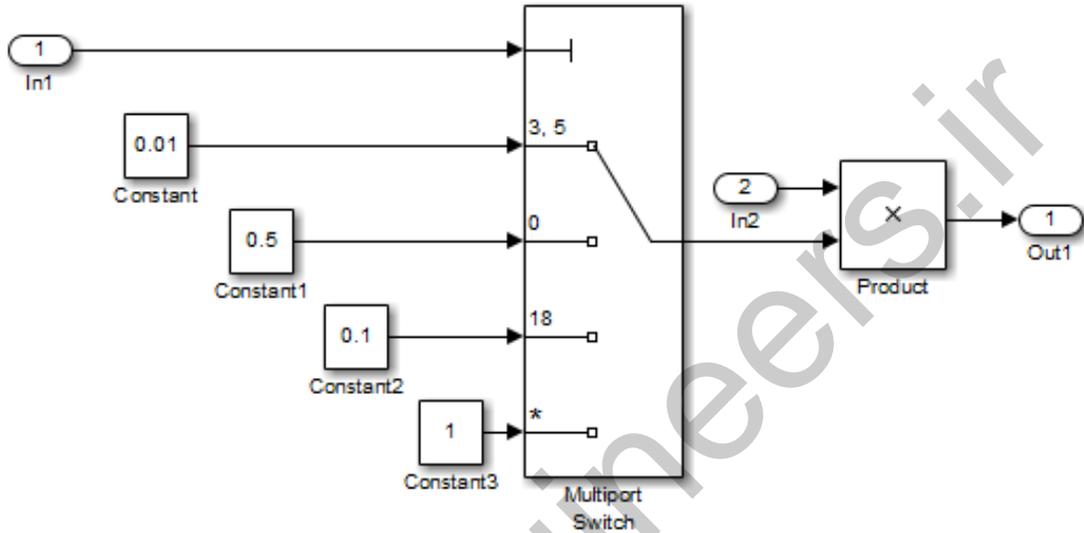

## Feedforward Fuel Rate

When you set **Data port for default case** to **Last data port**, the last data port includes a \* on the label. The comma and ellipsis after the \* indicate that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices LOW, RICH, or DISABLED. In this case, the Multiport Switch block outputs a value of 0.

### Noncontiguous Values for Data Port Indices

The following model uses a Multiport Switch block that specifies noncontiguous integer values for data ports.

The values of the indices are visible on the data port labels. You do not have to open the block dialog box to determine which value maps to each data port.

When you set **Data port for default case** to **Additional data port**, an extra port with a \* label appears. This port corresponds to the default case, which applies when the control input does not match the data port indices 3, 5, 0, or 18. In this case, the Multiport Switch block outputs a value of 1.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# MultiStateImage

Display an image that reflects an input value

**Library:** Dashboard

## Description

The MultiStateImage block allows you to use images to represent the states of signals during simulation.

To display data from a signal on the MultiStateImage block, double-click the MultiStateImage block to open the dialog box. Select a signal on the model canvas. The signal appears in the **Connection** table. Select the option button next to the signal whose state you want to capture. Click **Apply** to connect the signal to the block.

Using the **States** table, you can map signal input values to images.

## Limitations

The MultiStateImage block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to a MultiStateImage block, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the MultiStateImage block and reconnect the signal.

External mode simulation does not support the MultiStateImage block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection — Select a signal to connect and display

empty (default)

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

The table has a row for each signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### Scale Mode — Scaling of image

Fill with fixed Aspect Ratio (default) | Fixed | Fill

Specify how to scale an image as the block is resized. This parameter is applied to images as soon as they are added to the block.

Fixed

Do not resize the image

Fill

Resize the image to fill the block without maintaining aspect ratio

Fill with fixed Aspect Ratio

Resize the image to fill the block while maintaining aspect ratio

### States — Input signal values and their corresponding images

0 and undefined (default)

For each input value specified in the **State** column table, you can assign a corresponding image in the **Thumbnail** column.

Add states using the + button and remove states using the - button. To remove an image, click the X icon in the top-right corner of the image.

### Label — Position of block label

Top (default) | Bottom | Hide

Specify the position of the block label or instructional text if the block is not connected

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

Introduced in R2016b

Controlengineers.ir

## Mux

Combine several input signals into vector

## Library

Signal Routing

## Description

The Mux block combines its inputs into a single vector output. An input can be a scalar or vector signal. All inputs must be of the same data type and numeric type. The elements of the vector output signal take their order from the top to bottom, or left to right, input port signals. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations. To avoid adding clutter to a model, Simulink hides the name of a Mux block when you copy it from the Simulink library to a model. See “Mux Signals” for information about creating and decomposing vectors.

---

**Note:** To create a composite signal in which the constituent signals can have different data and numeric types, use a **Bus Creator** block.

---

## Data Type Support

The Mux block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Number of inputs

Specify number of inputs. You can also specify the size of inputs and the names of input signals.

#### Settings

**Default:** 2

You can enter a number or a comma-separated list of signal names for this parameter field.

Use the **Number of inputs** parameter to specify the number of input signals. You can also specify names and sizes. Use one of these formats.

Format	Block Behavior
Scalar	<p>Specifies the number of inputs to the Mux block.</p> <p>When you use this format, the block accepts scalar or vector signals of any size. Simulink assigns each input the name <code>signalN</code>, where N is the input port number.</p>
Vector	<p>The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input.</p> <p>A positive value specifies that the corresponding port can accept only vectors of that size. For example, <code>[2 3]</code> specifies two input ports of sizes 2 and 3, respectively. If an input signal width does not match the expected width, an error message appears. A value of -1 specifies that the corresponding port can accept scalars or vectors of any size.</p>
Cell array	<p>The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input.</p> <p>A scalar value N specifies a vector of size N. A value of -1 means that the corresponding port can accept scalar or vector signals of any size.</p>

Format	Block Behavior
Signal name list	You can enter a list of signal names separated by commas. Simulink assigns each name to the corresponding port and signal. For example, if you enter <code>position,velocity</code> , the Mux block has two inputs, named <code>position</code> and <code>velocity</code> .

**Tip:** If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, Simulink adds a port and updates the **Number of inputs** parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Display option

Specify the appearance of the block in the model.

### Settings

**Default:** bar

bar

Displays the block in a solid foreground color

none

Mux appears inside the block

signals

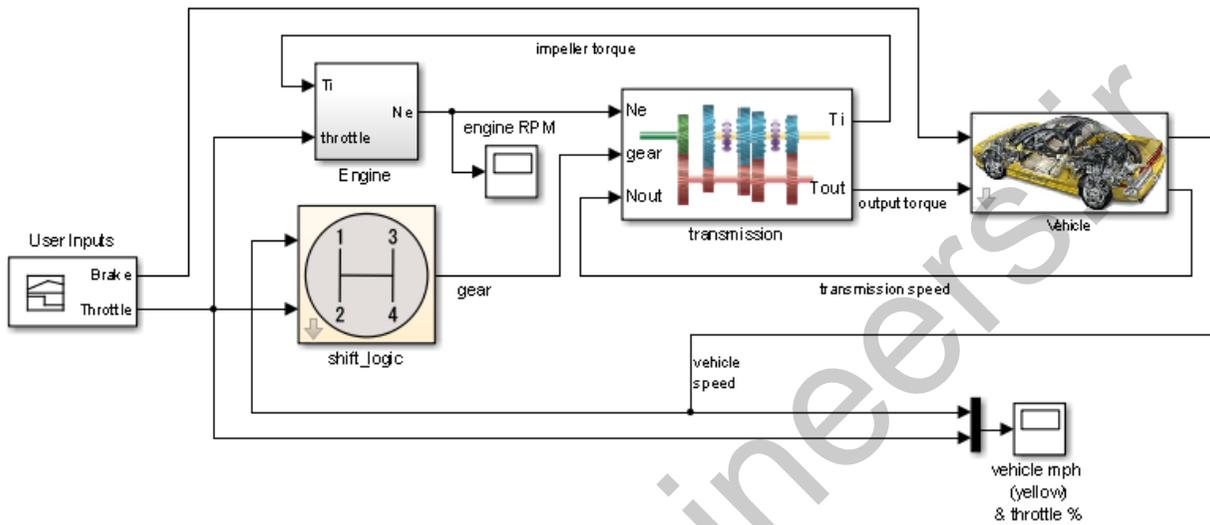

Displays signal names next to each port

### Command-Line Information

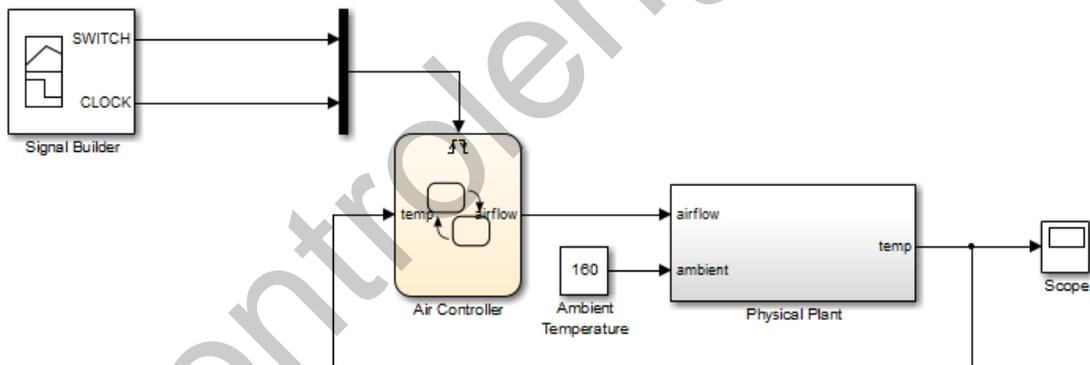

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Examples

The `sf_car` model uses a Mux block to combine two signals for input to a Scope block:

The sf\_aircontrol model uses a Mux block to combine two signals for input to a Stateflow chart:

The following models also show how to use the Mux block:

- sldemo\_auto\_climatecontrol
- sldemo\_susp
- sldemo\_zerxing
- penddemo

## Characteristics

Data types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Multidimensional signals	No
Variable-size signals	No
Code generation	Yes

## See Also

Demux

Introduced before R2006a

Controlengineers.ir

# Out Bus Element

Output signals from a subsystem as a virtual bus

**Library:** Ports & Subsystems

 OutBus.signal1

## Description

---

**Note:** This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Ports & Subsystems library — Out Bus Element
  - In the Signal Routing library — Bus Element Out
- 

To output signals in a virtual bus from a subsystem, use an Out Bus Element block for each signal in the subsystem that you want the bus to contain. This block integrates into one block the functionality of using an Outport block and a Bus Creator block. The Out Bus Element block is of the Outport block type. There are no specifications allowed on an Out Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and OutBusElement blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
  - For output, avoid a Goto, From, and Bus Creator block configuration.
  - For input, avoid a duplicate Outport blocks and a Bus Selector, Goto, and From block configuration.

To output multiple signals from a subsystem as a bus signal, create multiple Out Bus Element blocks, one for each signal. To add an Out Bus Element block, you can:

- Drag the block from the Library Browser. This creates a new port.

- Use quick insert. This creates a new port.
- Copy the block from an existing block. Either copy and paste or right-click and drag the block. Then specify whether to use the same port as the original block for new block or to create a new subsystem port.
- In the Block Parameters dialog box, click . To change the signal name, double-click the signal name in the tree view or in the icon text in the block diagram and edit the text.

If an Out Bus Element block creates a signal A, then another Out Bus Element block for the same port cannot specify signal A (or a child of signal A) as an element

To add a subbus, in the Block Parameters dialog box, click . To remove blocks associated with selected elements, click .

You can reorder bus elements by dragging and dropping a signal in the list of signals in the Block Parameters dialog box.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

## Ports

The block does not have an output port. Use the Block Parameters dialog box to specify the subsystem output port to which the block sends its input signal.

## Input

**Port\_1** — Input port for bus signal or bus element from within subsystem  
signal

The selected input signal is included in a bus signal that the subsystem outputs. The signal can have a real or complex values of any data type that Simulink supports.

## Parameters

**Port name** — Name of subsystem output port  
OutBus (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and Out Bus Element block icons. If you specify a port name, that name cannot already be in use by another block or port. All Out Bus Element blocks that access the same subsystem output port reflect the port name that you specify.

## Programmatic Use

**Block Parameter:** PortName

**Type:** text

**Default:** OutBus

### Port number — Order in which port appears for subsystem output ports

1 (default) | integer

Specify the order in which the port appears on the subsystem, with 1 being the top port, 2 the second port down, and so on.

- If you specify a number that exceeds the number of subsystem output ports, new ports are added above the port associated with the Outport Bus Element block.
- If you add an Out Bus Element block that creates another subsystem output port, the port number is the next available number.
- If you delete all Out Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

## Programmatic Use

**Block Parameter:** Port

**Value:** integer

**Default:** 1

Introduced in R2017a

Controlengineers.ir

## Output

Create output port for subsystem or external output

## Library

Ports & Subsystems, Sinks

## Description

Output blocks are the links from a system to a destination outside the system.

Simulink software assigns Output block port numbers according to these rules:

- It automatically numbers the Output blocks within a root-level system or subsystem sequentially, starting with 1.
- If you add an Output block, it is assigned the next available number.
- If you delete an Output block, other port numbers are automatically renumbered to ensure that the Output blocks are in sequence and that no numbers are omitted.

## Output Blocks in a Subsystem

Output blocks in a subsystem represent outputs from the subsystem. A signal arriving at an Output block in a subsystem flows out of the associated output port on that Subsystem block. The Output block associated with an output port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the output port on the Subsystem block. For example, the Output block whose **Port number** parameter is 1 sends its signal to the block connected to the topmost output port on the Subsystem block.

If you renumber the **Port number** of an Output block, the block becomes connected to a different output port, although the block continues to send the signal to the same block outside the subsystem.

When you create a subsystem by selecting existing blocks, if more than one Output block is included in the grouped blocks, Simulink software automatically rennumbers the ports on the blocks.

The Output block name appears in the Subsystem icon as a port label. To suppress display of the label, click the Output block and select **Format > Hide Name**.

---

**Tip:** For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Output with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The Out Bus Element block is of block type Output. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

---

## Initializing Output Blocks in Conditionally Executed Contexts

To set initial conditions for an Output block in a conditionally executed subsystem, use one of these approaches.

- Inherit initial values from input signals for the subsystem.
- Explicitly specify initial values

For details, see “Conditional Subsystem Initial Output Values”.

---

**Note:** If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an Initial Condition (IC) for the subsystem’s Output block. For more information, see “Underspecified initialization detection”.

---

## Top-level Outport Block in a Model Hierarchy

Outport blocks at the top-level of a model hierarchy have two uses: to supply external outputs to the base MATLAB workspace, which you can do by using either **Configuration Parameters** pane parameters or the `sim` command, and to provide a means for analysis functions to obtain output from the system.

- To supply external outputs to the workspace, use the **Configuration Parameters > Data Import/Export** pane (see Exporting Output Data to the MATLAB Workspace) or the `sim` command. For example, if a system has more than one Outport block and the save format is array, the following command

```
[t,x,y] = sim(...);
```

writes `y` as a matrix, with each column containing data for a different Outport block. The column order matches the order of the port numbers for the Outport blocks.

If you specify more than one variable name after the second (state) argument, data from each Outport block is written to a different variable. For example, if the system has two Outport blocks, to save data from Outport block 1 to `speed` and the data from Outport block 2 to `dist`, you could specify this command:

```
[t,x,speed,dist] = sim(...);
```

- To provide a means for the `linmod` and `trim` analysis functions to obtain output from the system (see “Linearizing Models”).

## Connecting Buses to Root-level Outports

A root-level Outport of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

If you want a root-level Outport of a model to accept a bus signal that contains mixed types, you must set the Outport block **Data type** parameter to use a bus object name for the **Bus:** `<object name>` or `<data type expression>` option, to define the type of bus that the Outport produces. If the bus signal is virtual, it will be converted to nonvirtual, as described in “Bus Conversion”. For more information, see “When to Use Bus Objects”.

## Associate Root-Level Outport Block with Simulink.Signal Object

To associate a root-level Outport block with a Simulink.Signal object, use the Model Data Editor. See “For Signals”.

## Data Type Support

The Outport block accepts real or complex signals of any data type that Simulink supports. An Outport block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as those of its input. The Outport block also accepts a bus object as a data type.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see Simulink.BusElement.

---

For more information, see “Data Types Supported by Simulink”.

The elements of a signal array connected to an Outport block can be of differing complexity and data types except in the following circumstance: If the output port is in a conditionally executed subsystem and the initial output is specified, all elements of an input array must be of the same complexity and data types.

Typical Simulink data type conversion rules apply to an output port's **Initial output** parameter. If the initial output value is in the range of the block's output data type, Simulink software converts the initial output to the output data type. If the specified initial output is out of the range of the output data type, Simulink software halts the simulation and signals an error.

## Parameters

- “Port number” on page 1-471

- “Signal name” on page 1-1129
- “Icon display” on page 1-834
- “Ensure output is virtual” on page 1-1130
- “Source of initial output value” on page 1-1132
- “Output when disabled” on page 1-1133
- “Initial output” on page 1-1134
- “Minimum” on page 1-840
- “Maximum” on page 1-841
- “Data type” on page 1-1137
- “Show data type assistant” on page 1-112
- “Mode” on page 1-1140
- “Data type override” on page 1-198
- “Signedness” on page 1-199
- “Word length” on page 1-200
- “Scaling” on page 1-193
- “Fraction length” on page 1-201
- “Slope” on page 1-202
- “Bias” on page 1-202
- “Lock output data type setting against changes by the fixed-point tools” on page 1-203
- “Output as nonvirtual bus in parent model” on page 1-1148
- “Unit (e.g., m, m/s<sup>2</sup>, N\*m)” on page 1-854
- “Port dimensions (-1 for inherited)” on page 1-1151
- “Variable-size signal” on page 1-1152
- “Sample time (-1 for inherited)” on page 1-857
- “Signal type” on page 1-1154

## Port number

Specify the port number of the block.

### Settings

**Default:** 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Signal name

Specify the name of the corresponding signal data in the generated code. Use this parameter to specify a name for the signal data when you apply a storage class to a root-level Outport block by using **View > Model Data**.

### Settings

**Default:** '' (empty character vector)

Specify a name by using text.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Icon display

Specify the information to be displayed on the icon of this input port.

### Settings

**Default:** Port number

Signal name

Display the name of the signal connected to this port (or signals if the input is a bus).

Port number

Display port number of this port.

Port number and signal name

Display both the port number and the names of the signals connected to this port.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Ensure output is virtual

This parameter applies to these blocks:

- Conditional subsystem
- Assignment
- Merge
- Model with root Outport block

### Settings

**Default:** Clear

Clear

Use signal buffer on output port. This buffer ensures consistent initialization of the Outport block signal.

Select

Simulink tries to remove the signal buffer.

- If the signal buffer is not needed, Simulink remove the buffer.
- If the signal buffer is needed for data consistency and proper execution, Simulink displays an error indicating the buffer could not be removed.

Allow partial writes through Assignment blocks.

Controlengineers.ir

## Source of initial output value

Select the source of the initial output value of the block.

### Settings

**Default:** Dialog

#### Dialog

The initial output value is specified by the **Initial output** parameter on the dialog.

#### Input signal

The initial output value is inherited from the input signal. See “Conditional Subsystem Initial Output Values”.

### Tips

- If you are using classic initialization mode, selecting **Input signal** will cause an error. To inherit the initial output value from the input signal, set this parameter to **Dialog** and specify [ ] (empty matrix) for the **Initial output** value. For more information, see “Conditional Subsystem Initial Output Values”.

### Dependencies

This parameter is enabled when the Output resides in an Conditional Subsystem.

Selecting Dialog enables the following parameters:

- **Output when disabled**
- **Initial output**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output when disabled

Specify what happens to the block output when the subsystem is disabled.

### Settings

**Default:** held

held

Output is held when the subsystem is disabled.

reset

Output is reset to the value given by **Initial output** when the subsystem is disabled.

### Tips

- When connecting the output of a conditional subsystem to a Merge block, set this parameter to **held**. Setting it to **reset** will return an error.

### Dependencies

- Selecting Dialog in **Source of initial output value** enables this parameter.
- This parameter is enabled when the Outport resides in a conditional subsystem with valid enabling and disabling semantics. For example, this parameter is disabled when the Outport is placed inside a Triggered Subsystem but is enabled when the Outport is placed inside an Enabled Subsystem.
- If an Outport is placed inside a function-call subsystem, this parameter is meaningful only if the function-call subsystem is bound to a state in a Stateflow chart. For more information, see “Bind a Function-Call Subsystem to a State” (Stateflow).

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Initial output

For conditionally executed subsystems, specify the block output before the subsystem executes and while it is disabled.

### Settings

**Default:** [ ]

Simulink software does not allow the initial output of this block to be `inf` or `NaN`.

### Tips

- Specify [ ] (empty matrix) to inherit the initial output value from the input signal. For more information, see “Conditional Subsystem Initial Output Values”.
- For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”

### Dependencies

- Selecting **Dialog** in **Source of initial output value** enables this parameter.
- This parameter is enabled when the Outport resides in an Conditional Subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Minimum

Specify the minimum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

---

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Data type

Specify the output data type of the external input.

### Settings

**Default:** Inherit: auto

Inherit: auto

A rule that inherits a data type

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Data type is enumerated, for example, Enum: BasicColors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example Simulink.NumericType

Do not specify a bus object as the expression.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rule for data types. Selecting **Inherit** enables a second menu/text box to the right.

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

## Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

## Dependency

Clicking the **Show data type assistant** button enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

ControlEngineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Output as nonvirtual bus in parent model

Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

### Settings

**Default:** Off

On

Select this parameter if you want the bus emerging in the parent model to be nonvirtual.

Off

Clear this parameter if you want the bus emerging in the parent model to be virtual.

### Tips

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see “Connect Multi-Rate Buses to Referenced Models”.
- For a virtual bus, to use a multirate signal, in the root-level Outport block, set the **Sample time** parameter to inherited (-1).
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

### Dependency

Selecting **Data type** > Bus: <object name> enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Unit (e.g., m, m/s<sup>2</sup>, N\*m)

Specify physical unit of the input signal to the block.

### Settings

**Default:** inherit

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a **Unit System Configuration** block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a **Unit System Configuration** block does not exist in the component, the **Model Configuration Parameters** dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Port dimensions (-1 for inherited)

Specify the dimensions that a signal must have in order to be connected to this Output block.

### Settings

**Default:** -1

Valid values are:

-1	A signal of any dimensions can be connected to this port.
N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Variable-size signal

Specify the type of signals allowed out of this port.

### Settings

**Default:** Inherit

Inherit

Allow variable-size and fixed-size signals.

No

Do not allow variable-size signals.

Yes

Allow only variable-size signals.

### Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

### Command-Line Information

**Parameter:** VarSizeSig

**Type:** character vector

**Value:** 'Inherit' | 'No' | 'Yes'

**Default:** 'Inherit'

## Sample time (-1 for inherited)

Enter the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

### Settings

**Default:** -1

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

See also “Specify Sample Time” in the online documentation for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Signal type

Specify the numeric type of the signal output by this block.

### Settings

**Default:** auto

auto

Output the numeric type of the signal that is connected to its input.

real

Output a real-valued signal. The signal connected to this block must be real. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

complex

Output a complex signal. The signal connected to this block must be complex. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from the driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

- Inport
- Out Bus Element
- “Simplify Subsystem Bus Interfaces”

**Introduced before R2006a**

## Permute Dimensions

Rearrange dimensions of multidimensional array dimensions

### Library

Math Operations

### Description

The block reorders the elements of the input signal so that they are in the order you specify in the **Order** parameter.

### Data Type Support

This block accepts signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. Output must be the same data type as the input.

You can use an array of buses as an input signal to a Permute Dimensions block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

**Order**

Specify the permutation order to apply to the dimensions of the input signal. This parameter is a vector of elements, where the number of elements in the vector is the number of dimensions of the input signal.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Math Function (transpose), permute (in the MATLAB reference documentation)

Introduced in R2007a

## PID Controller Discrete PID Controller

Simulate continuous- or discrete-time PID controllers

### Library

Continuous, Discrete

### Description

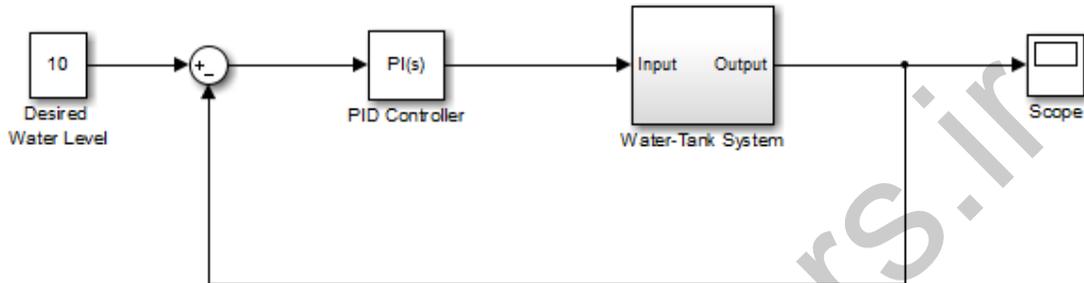

Implement a continuous- or discrete-time controller (PID, PI, PD, P, or I) in your Simulink model. PID controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design™ software (**PID Tuner** or **Control System Designer**).

The PID Controller block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

Configurable options in the PID Controller block include:

- Controller type (PID, PI, PD, P, or I)
- Controller form (Parallel or Ideal)
- Time domain (continuous or discrete)
- Initial conditions and reset trigger
- Output saturation limits and built-in anti-windup mechanism
- Signal tracking for bumpless control transfer and multiloop control

In one common implementation, the PID Controller block operates in the feedforward path of the feedback loop:

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see the [PID Controller \(2 DOF\)](#) block reference page.

You can generate code to implement your controller using any Simulink data type, including fixed-point data types. (Code generation requires Simulink Coder software; fixed-point implementation requires the Fixed-Point Designer product.)

For examples illustrating some applications of the PID Controller block, see the following Simulink examples:

- [Anti-Windup Control Using a PID Controller](#)
- [Bumpless Control Transfer Between Manual and PID Control](#)

## Data Type Support

The PID Controller block accepts real signals of any numeric data type that Simulink software supports, including fixed-point data types. See “Data Types Supported by Simulink” in the Simulink documentation for more information.

## Parameters

The following table summarizes the PID Controller block parameters, accessible on the block parameter dialog box.

Task	Parameters
Choose controller form and type.	<ul style="list-style-type: none"> <li>• <b>Controller Form</b> in Main tab</li> <li>• <b>Controller</b></li> </ul>

Task	Parameters
Choose discrete or continuous time.	<ul style="list-style-type: none"> <li>• <b>Time-domain</b></li> <li>• <b>Sample time</b></li> </ul>
Choose an integration method (discrete time).	<ul style="list-style-type: none"> <li>• <b>Integrator method</b></li> <li>• <b>Filter method</b></li> </ul>
Set and tune controller gains.	<ul style="list-style-type: none"> <li>• <b>Controller Parameters Source</b> in Main tab</li> <li>• <b>Proportional (P)</b> in Main tab</li> <li>• <b>Integral (I)</b> in Main tab</li> <li>• <b>Derivative (D)</b> in Main tab</li> <li>• <b>Filter coefficient (N)</b> in Main tab</li> <li>• <b>Use filtered derivative</b> in Main tab</li> </ul>
Set integrator and filter initial conditions.	<ul style="list-style-type: none"> <li>• <b>Initial conditions Source</b> in Main tab</li> <li>• <b>Integrator Initial condition</b> in Main tab</li> <li>• <b>Filter Initial condition</b> in Main tab</li> <li>• <b>Initial condition setting</b> (command line only)</li> <li>• <b>External reset</b> in Main tab</li> <li>• <b>Ignore reset when linearizing</b> in Main tab</li> </ul>
Limit block output.	<ul style="list-style-type: none"> <li>• <b>Limit output</b> in PID Advanced tab</li> <li>• <b>Lower saturation limit</b> in PID Advanced tab</li> <li>• <b>Upper saturation limit</b> in PID Advanced tab</li> <li>• <b>Ignore saturation when linearizing</b> in PID Advanced tab</li> </ul>
Configure anti-windup mechanism (when you limit block output).	<ul style="list-style-type: none"> <li>• <b>Anti-windup method</b> in PID Advanced tab</li> <li>• <b>Back-calculation gain (Kb)</b> in PID Advanced tab</li> </ul>

Task	Parameters
Enable signal tracking.	<ul style="list-style-type: none"> <li>• <b>Enable tracking mode</b> in PID Advanced tab</li> <li>• <b>Tracking gain (Kt)</b> in PID Advanced tab</li> </ul>
Configure data types.	<ul style="list-style-type: none"> <li>• <b>Parameter data type</b> in Data Type Attributes tab</li> <li>• <b>Product output data type</b> in Data Type Attributes tab</li> <li>• <b>Summation output data type</b> in Data Type Attributes tab</li> <li>• <b>Accumulator data type</b> in Data Type Attributes tab</li> <li>• <b>Integrator output data type</b> in Data Type Attributes tab</li> <li>• <b>Filter output data type</b> in Data Type Attributes tab</li> <li>• <b>Saturation output data type</b> in Data Type Attributes tab</li> <li>• <b>Lock output data type setting against changes by the fixed-point tools</b> in Data Type Attributes tab</li> <li>• <b>Saturate on integer overflow</b> in Data Type Attributes tab</li> <li>• <b>Integer rounding mode</b> in Data Type Attributes tab</li> </ul>
Configure block for code generation.	<ul style="list-style-type: none"> <li>• <b>State name</b> in State Attributes tab</li> <li>• <b>State name must resolve to Simulink signal object</b> in State Attributes tab</li> <li>• <b>Code generation storage class</b> in State Attributes tab</li> <li>• <b>Code generation storage type qualifier</b> in State Attributes tab</li> </ul>

## Controller form

Select the controller form.

### Settings

#### Parallel (Default)

Selects a controller form in which the output is the sum of the proportional, integral, and derivative actions, weighted according to the independent gain parameters **P**, **I**, and **D**. The filter coefficient **N** sets the location of the pole in the derivative filter. For a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = \left[ P + I \left( \frac{1}{s} \right) + D \left( \frac{Ns}{s + N} \right) \right]$$

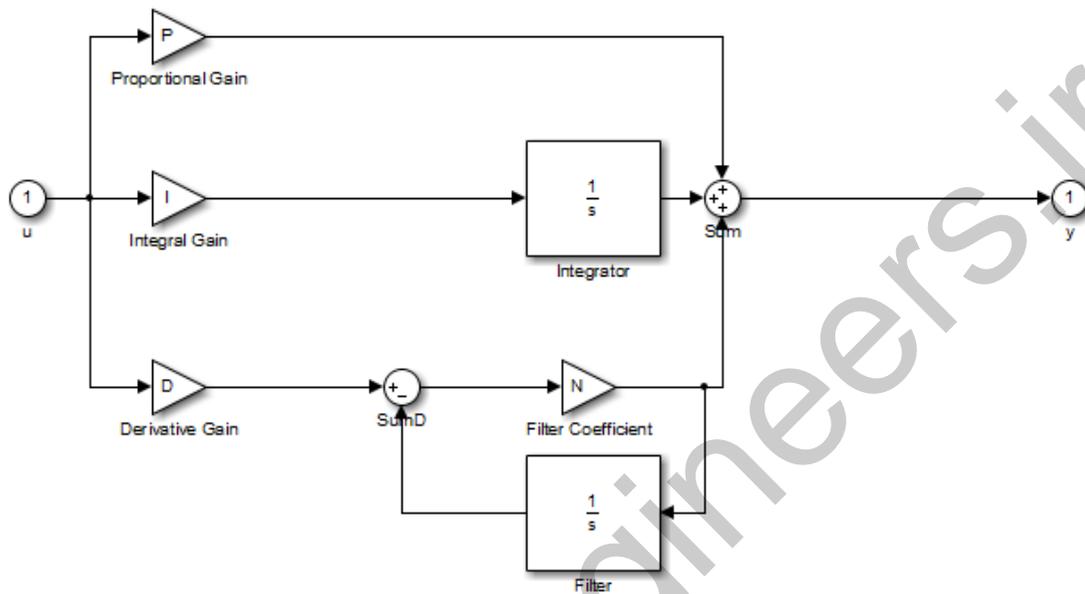

For a discrete-time parallel PID controller, the transfer function takes the form:

$$C_{par}(z) = P + Ia(z) + D \left[ \frac{N}{1 + Nb(z)} \right]$$

where the **Integrator method** determines  $a(z)$  and the **Filter method** determines  $b(z)$  (for sampling time  $T_s$ ):

	Forward Euler method	Backward Euler method	Trapezoidal method
$a(z)$ (determined by Integrator method)	$\frac{T_s}{z-1}$	$\frac{T_s z}{z-1}$	$\frac{T_s}{2} \frac{z+1}{z-1}$
$b(z)$ (determined by Filter method)	$\frac{T_s}{z-1}$	$\frac{T_s z}{z-1}$	$\frac{T_s}{2} \frac{z+1}{z-1}$

The controller transfer function for the current settings is displayed in the block dialog box.

### Parallel PID Controller

#### Ideal

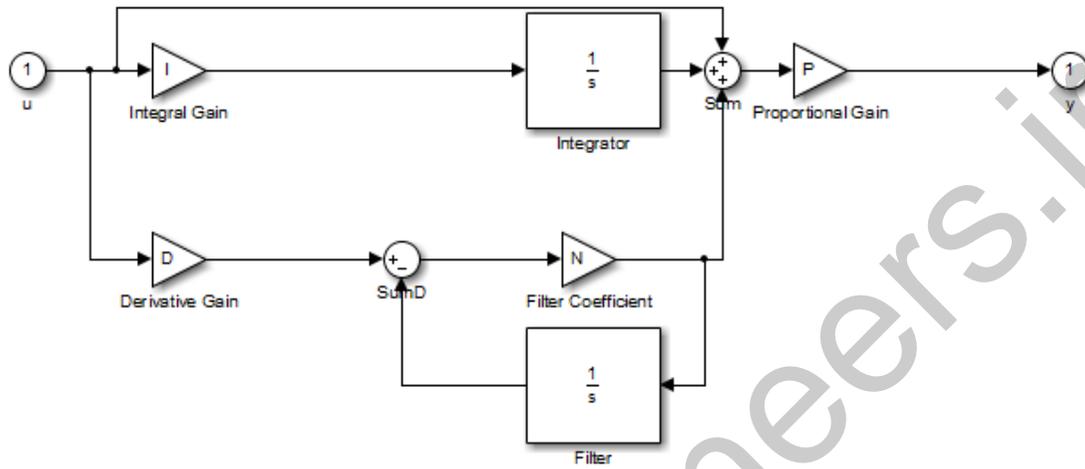

Selects a controller form in which the proportional gain  $P$  acts on the sum of all actions. The transfer functions are the same as for the parallel form, except that  $P$  multiplies all terms. For a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P \left[ 1 + I \left( \frac{1}{s} \right) + D \left( \frac{Ns}{s+N} \right) \right]$$

For a discrete-time ideal PID controller the transfer function is:

$$C_{id}(z) = P \left[ 1 + Ia(z) + D \frac{N}{1 + Nb(z)} \right]$$

where the **Integrator method** determines  $a(z)$  and the **Filter method** determines  $b(z)$  as described previously for the parallel controller form.

Ideal PID Controller

## Controller

Specify the controller type.

### Settings

PID (Default)

Implements a controller with proportional, integral, and derivative action.

PI

Implements a controller with proportional and integral action.

PD

Implements a controller with proportional and derivative action.

P

Implements a controller with proportional action.

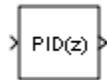

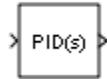

I

Implements a controller with integral action.

The controller transfer function for the current settings is displayed in the block dialog box.

## Time-domain

Select continuous or discrete time domain. The appearance of the block changes to reflect your selection.

### Settings

#### Continuous-time (Default)

Selects the continuous-time representation.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

#### Discrete-time

Selects the discrete-time representation. Selecting **Discrete-time** also allows you to specify the:

- **Sample time**, which is the discrete interval between samples.
- Discrete integration methods for the integrator and the derivative filter using the **Integrator method** and **Filter method** menus.

## Integrator method

(Available only when you set **Time-domain** to **Discrete-time**.) Specify the method used to compute the integrator output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

### Settings

#### Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the **Forward Euler** method can result in instability, even when discretizing a system that is stable in continuous time.

#### Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the **Backward Euler** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

If you activate the **Back-calculation Anti-windup method**, this integration method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

#### Trapezoidal

Selects the Bilinear approximation.

An advantage of the **Trapezoidal** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the **Trapezoidal** method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

If you activate the **Back-calculation Anti-windup method**, this integration method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a

model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

controlengineers.ir

## Filter method

(Available only when you set **Time-domain** to **Discrete-time**.) Specify the method used to compute the derivative filter output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

### Settings

#### Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the **Forward Euler** method can result in instability, even when discretizing a system that is stable in continuous time.

#### Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the **Backward Euler** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value  $N > 0$  yields a stable result with this method.

This filter method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

#### Trapezoidal

Selects the Bilinear approximation.

An advantage of the **Trapezoidal** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value  $N > 0$  yields a stable result with this method. Of all available filter methods, the **Trapezoidal** method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

This filter method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code

using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

controlengineers.ir

## Sample time (-1 for inherited)

(Available only when you set **Time-domain** to Discrete-time.) Specify the discrete interval between samples.

### Settings

#### Default: 1

By default, the block uses a discrete sample time of 1. To specify a different sample time, enter another discrete value, such as 0.1.

If you specify a value of -1, the PID Controller block inherits the sample time from the upstream block. Do not enter a value of 0; to implement a continuous-time controller, select the **Time-domain** Continuous-time.

See “Specify Sample Time” in the online documentation for more information.

Controlengineers.ir

## Controller Parameters Source

Select the source of the controller gains and filter coefficient. You can provide these parameters explicitly in the block dialog box, or enable external inputs for them on the block. Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control, in which controller gains are determined by logic or other calculation in the Simulink model and passed to the block.

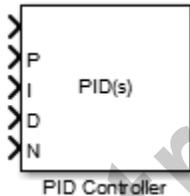

### Settings

**internal** (Default)

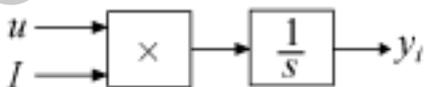

Specify the PID gains and filter coefficient explicitly using the **P**, **I**, **D**, and **N** parameters.

**external**

Specify the PID gains and filter coefficient externally. An additional input port appears under the block input for each parameter that is required for the current controller type:

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because of the way the PID gains are implemented within the block. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the block's input signal is multiplied by the externally-supplied integrator gain,  $I$ , before integration. This implementation yields:

$$y_i = \int u I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain  $D$  to be differentiated.

Controlengineers.ir

## Proportional (P)

(Available for PID, PD, PI, and P controllers.) Specify the proportional gain  $P$ .

**Default:** 1

Enter a finite, real gain value into the **Proportional (P)** field. Use either scalar or vector gain values. For a **Parallel PID Controller form**, the proportional action is independent of the integral and derivative actions. For an **Ideal PID Controller form**, the proportional action acts on the integral and derivative actions. See “Controller form” on page 1-1162 for more information about the role of  $P$  in the controller transfer function.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

## Integral (I)

(Available for PID, PI, and I controllers.) Specify the integral gain  $I$ .

**Default:** 1

Enter a finite, real gain value into the **Integral (I)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

ControlEngineers.ir

## Derivative (D)

(Available for PID and PD controllers.) Specify the derivative gain D.

**Default:** 0

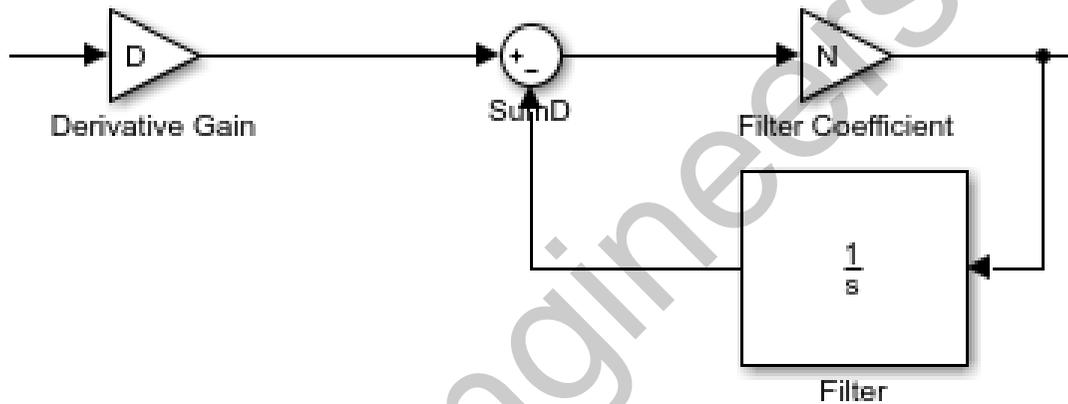

Enter a finite, real gain value into the **Derivative (D)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

Controlengineers.ir

## Filter coefficient (N)

(Available for PID and PD controllers, when **Use filtered derivative** is checked.)  
 Specify the filter coefficient N, which determines the pole location of the filter in the derivative action:

The filter pole falls at  $s = -N$  in the **Continuous-time Time-domain**. For **Discrete-time**, the location of the pole depends on which **Filter method** you select (for sampling time  $T_s$ ):

- Forward Euler:

$$z_{pole} = 1 - NT_s$$

- Backward Euler:

$$z_{pole} = \frac{1}{1 + NT_s}$$

- Trapezoidal:

$$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$$

**Default:** 100.

Enter a finite, real gain value into the **Filter Coefficient (N)** field. Use either scalar or vector gain values. Note that the PID controller block does not support  $N = \infty$  (ideal unfiltered derivative).

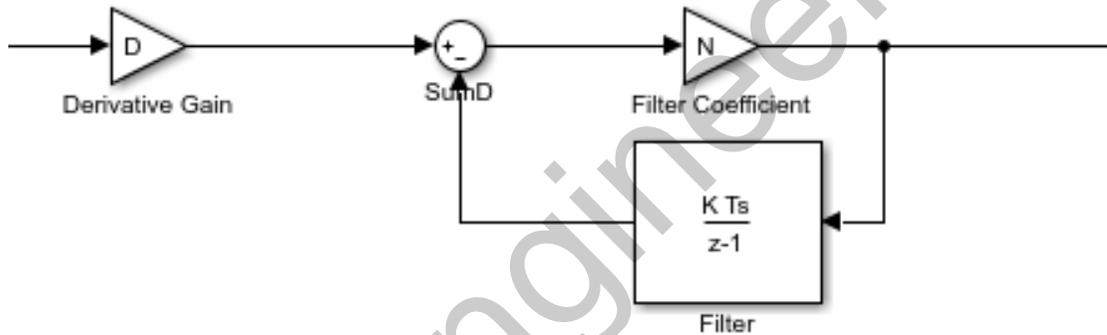

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design). Automatic tuning requires  $N > 0$ .

Controlengineers

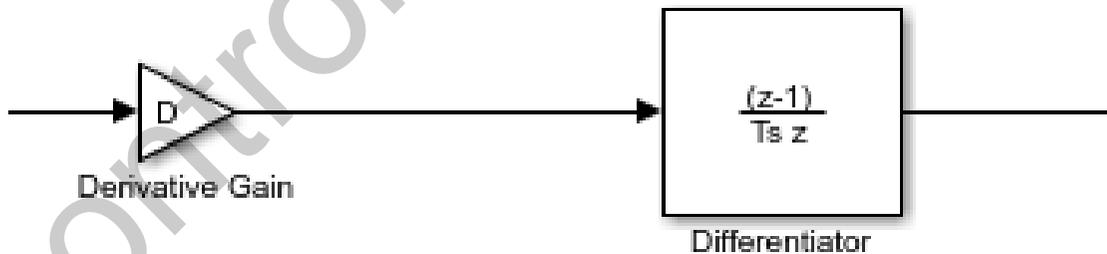

## Use Filtered Derivative

Specify whether derivative term is filtered (finite N) or unfiltered. Unfiltered derivative is available only for discrete-time controllers.

Unchecking this option replaces the filtered derivative with a discrete differentiator. For example, if **Filter Method** is Forward Euler, then the filtered derivative term is represented by:

When you uncheck **Use filtered derivative**, the derivative term becomes:

### Settings

- On (Default)  
Use derivative filter (finite N).

Off

Derivative is unfiltered.

controlengineers.ir

## Initial conditions Source

(Only available for controllers with integral or derivative action.) Select the source of the integrator and filter initial conditions. Simulink uses initial conditions to initialize the integrator and filter output at the start of a simulation or at a specified trigger event (See “External reset” on page 1-1185). The integrator and filter initial conditions in turn determine the initial block output.

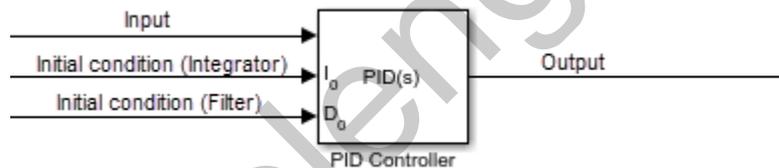

### Settings

internal (Default)

Specifies the integrator and filter initial conditions explicitly using the **Integrator Initial condition** and **Filter Initial condition** parameters.

external

Specifies the integrator and filter initial conditions externally. An additional input port appears under the block input for each initial condition:  $I_0$  for the integrator and  $D_0$  for the filter:

## Integrator Initial condition

(Available only when **Initial conditions Source** is **internal** and the controller includes integral action.) Specify the integrator initial value. Simulink uses the initial condition to initialize the integrator output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1185). The integrator initial condition, together with the filter initial condition, determines the initial output of the PID controller block.

**Default:** 0

Simulink does not permit the integrator initial condition to be `inf` or `NaN`.

Controlengineers

## Filter Initial condition

(Available only when **Initial conditions Source** is **internal**, the controller includes derivative action, and **Use filtered derivative** is checked.) Specify the filter initial value. Simulink uses the initial condition to initialize the filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1185). The filter initial condition, together with the integrator initial condition, determines the initial output of the PID controller block.

**Default:** 0

Simulink does not permit the filter initial condition to be `inf` or `NaN`.

Controlengineers.ir

## Initial condition setting

Specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. This parameter can be changed only at the command line using `set_param` to set the `InitialConditionSetting` parameter of the block.

### Settings

State (most efficient) (Default)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

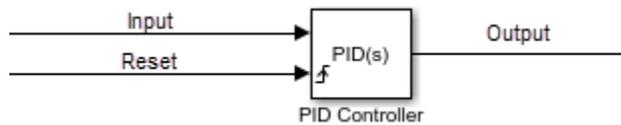

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

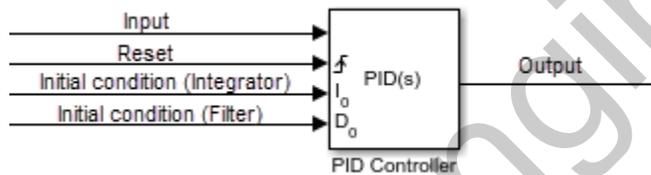

For more information about the **Initial condition setting** parameters, see the `Discrete-Time Integrator` block.

## External reset

Select the trigger event that resets the integrator and filter outputs to the initial conditions you specify in the **Integrator Initial condition** and **Filter Initial condition** fields. Selecting any option other than none enables a reset input on the block for the external reset signal, as shown:

Or, if the **Initial conditions Source** is External,

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

---

**Note:** To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

---

## Settings

`none` (Default)

Does not reset the integrator and filter outputs to initial conditions.

`rising`

Resets the outputs when the reset signal has a rising edge.

`falling`

Resets the outputs when the reset signal has a falling edge.

either

Resets the outputs when the reset signal either rises or falls.

level

Resets and holds the outputs to the initial conditions while the reset signal is nonzero.

controlengineers.ir

## Ignore reset when linearizing

Force Simulink linearization commands to ignore any reset mechanism that you have chosen with the **External reset** menu. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the PID Controller block to reset.

### Settings

- Off (Default)  
Simulink linearization commands do not ignore states corresponding to the reset mechanism.
- On  
Simulink linearization commands ignore states corresponding to the reset mechanism.

## Enable zero-crossing detection

Enable zero-crossing detection in continuous-time models upon reset and upon entering or leaving a saturation state.

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate an **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

On (Default)

Uses zero-crossing detection at any of the following events: reset; entering or leaving an upper saturation state; and entering or leaving a lower saturation state.

Off

Does not use zero-crossing detection.

Enabling zero-crossing detection for the PID Controller block also enables zero-crossing detection for all under-mask blocks that include the zero-crossing detection feature.

## Limit output

Limit the block output to values you specify as the **Lower saturation limit** and **Upper saturation limit** parameters.

Activating this option limits the block output internally to the block, obviating the need for a separate Saturation on page 1-1491 block after the controller in your Simulink model. It also allows you to activate the block's built-in anti-windup mechanism (see “Anti-windup method” on page 1-1192).

### Settings

Off (Default)

Does not limit the block output, which equals the weighted sum of the proportional, integral, and derivative actions.

On

Limits the block output to the **Lower saturation limit** or the **Upper saturation limit** whenever the weighted sum exceeds those limits. Allows you to select an **Anti-windup method**.

## Lower saturation limit

(Available only when you select the **Limit output** check box.) Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

**Default:** -inf

controlengineers.ir

## Upper saturation limit

(Available only when you select the **Limit output** check box.) Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

**Default:** inf

Controlengineers.ir

## Anti-windup method

(Available only when you select the **Limit output** option and the controller includes integral action.) Select an anti-windup mechanism to discharge the integrator when the block is saturated, which occurs when the sum of the block components exceeds the output limits.

When you select the **Limit output** check box and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator wind-up), increasing the difference between the block output and the sum of the block components. Without a mechanism to prevent integrator wind-up, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to discharge the integrator and return the weighted sum within the block saturation limit.

In both cases, controller performance can suffer. To combat the effects of wind-up without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. Activating an anti-windup mechanism can improve controller performance.

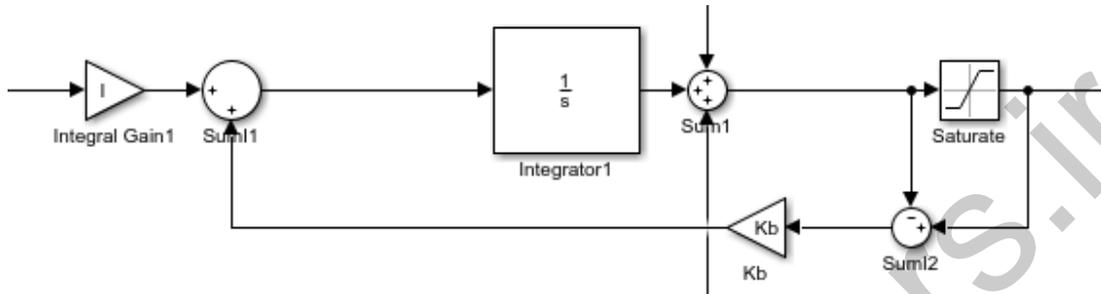

### Settings

none (Default)

Does not use an anti-windup mechanism. This setting may cause the block's internal signals to be unbounded even if the output appears to be bounded by the saturation limits. This can result in slow recovery from saturation or unexpected overflows.

back-calculation

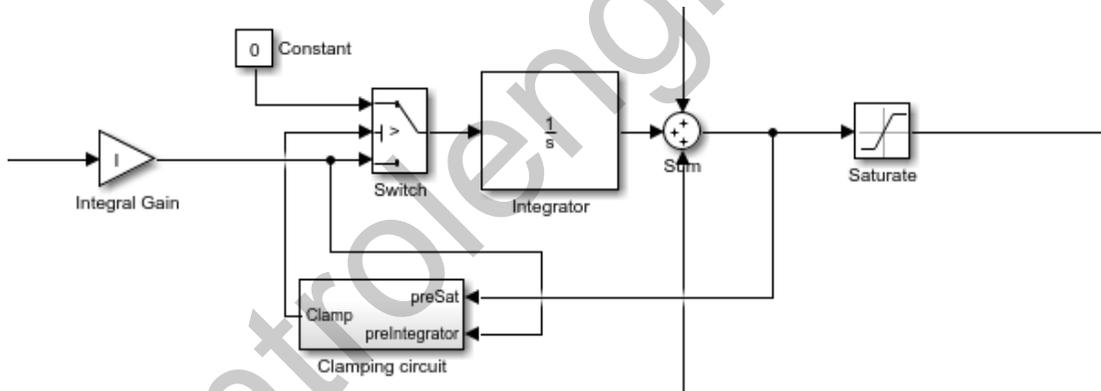

Discharges the integrator when the block output saturates using the integral-gain feedback loop:

You can also specify a value for the **Back-calculation coefficient (Kb)**.

clamping

Stops integration when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Resumes integration when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. The integrator portion of the block is:

The clamping circuit implements the logic necessary to determine whether integration continues.

## Back-calculation gain (Kb)

(Available only when the back-calculation **Anti-windup method** is active.) Specify the gain coefficient of the anti-windup feedback loop.

The back-calculation anti-windup method discharges the integrator on block saturation using a feedback loop having gain coefficient Kb.

**Default:** 1

Controlengineers.ir

## Ignore saturation when linearizing

Force Simulink linearization commands ignore PID Controller block output limits. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the PID Controller block to exceed the output limits.

### Settings

On (Default)

Simulink linearization commands ignore states corresponding to saturation.

Off

Simulink linearization commands do not ignore states corresponding to saturation.

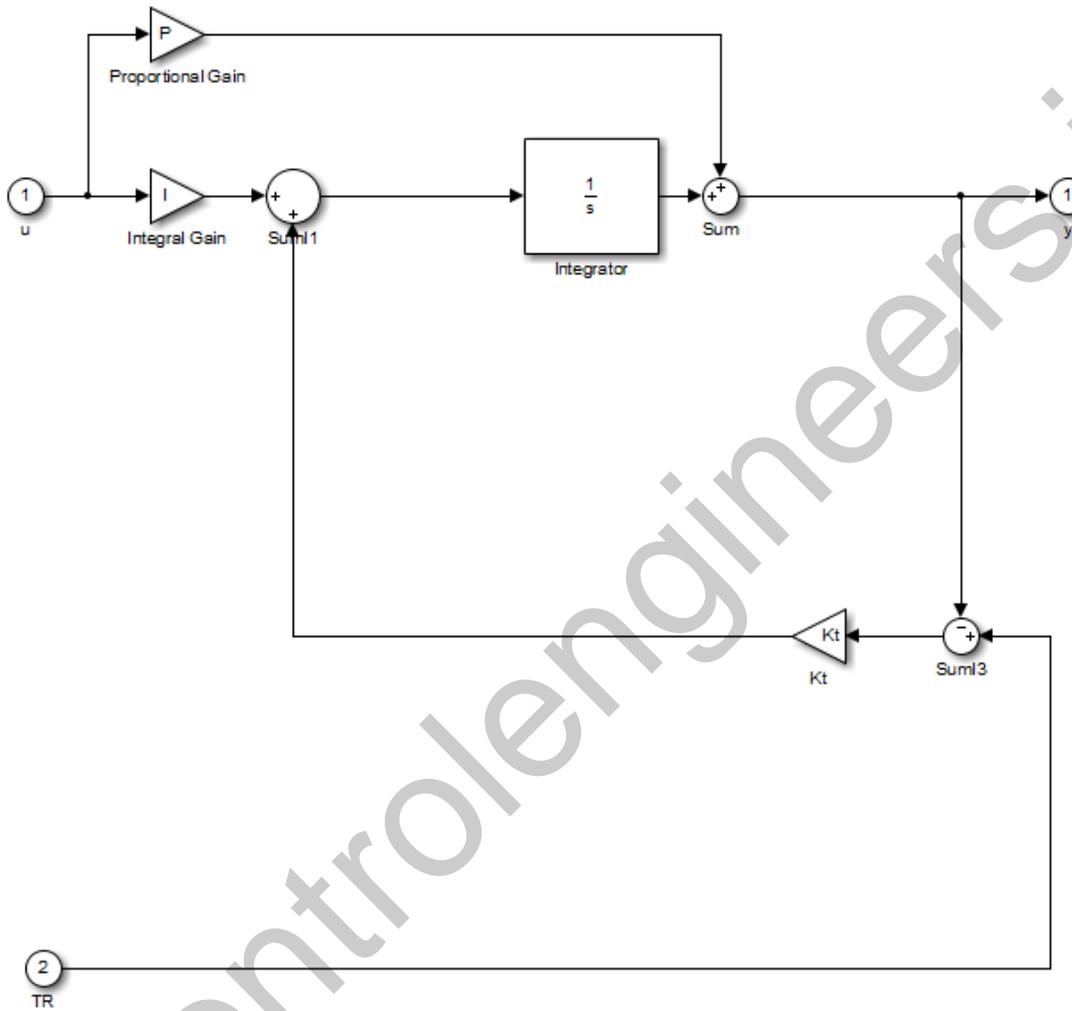

Controlengineers.ir

## Enable tracking mode

(Available for any controller with integral action.) Activate signal tracking, which lets the output of the PID Controller block follow a tracking signal. Provide the tracking signal to the block at the TR port, which becomes active when you select **Enable tracking mode**.

When signal tracking is active, the difference between the tracked signal and the block output is fed back to the integrator input with a gain  $K_t$ . The structure is illustrated for a PI controller:

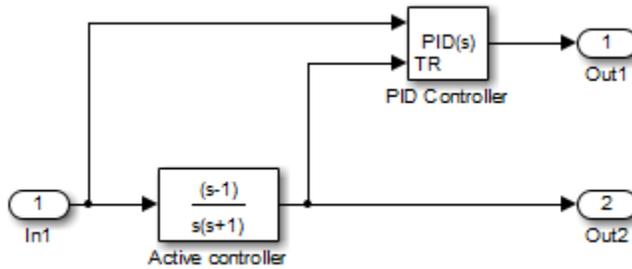

Controlengineers.ir

You can also specify the **Tracking coefficient (Kt)**.

### Bumpless control transfer

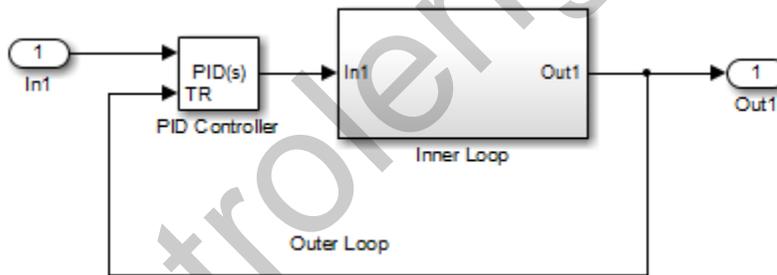

Use signal tracking, for example, to achieve bumpless control transfer in systems that switch between two controllers. You can make one controller track the output of the other controller by connecting the TR port to the signal you want to track. For example:

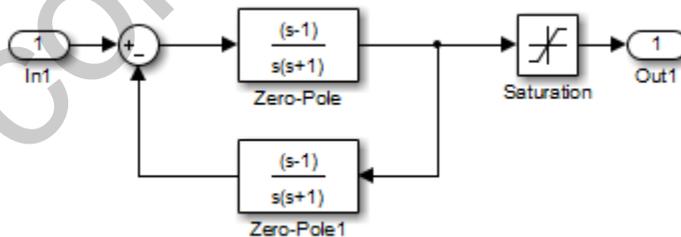

In this example, the outputs Out1 and Out2 can drive a controlled system (not shown) through a switch that transfers control between the “Active controller” block and the PID Controller block. The signal tracking feature of the PID Controller block provides smooth operation upon transfer of control from one controller to another, ensuring that the two controllers have the same output at the time of transfer.

**Multiloop control**

Use signal tracking to prevent block wind-up in multiloop control approaches, as this example illustrates:

The inner-loop subsystem contains the following blocks:

In this example, the inner loop has an effective gain of 1 when it does not saturate. Without signal tracking, the inner loop winds up in saturation. Signal tracking ensures that the PID Controller output does not exceed the saturated output of the inner loop.

### Settings

- Off (Default)  
Disables signal tracking and removes TR block input.
- On  
Enables signal tracking and activates TR input.

Controlengineers.ir

## Tracking gain (Kt)

(Available only when you select **Enable tracking mode**.) Specify Kt, which is the gain of the signal tracking feedback loop.

**Default:** 1

controlengineers.ir

## Parameter data type

Select the data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

**Inherit: Inherit via internal rule (Default)**

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit: Inherit via back propagation**

Use data type of the driving block.

**Inherit: Same as input**

Use data type of input signal.

`double`

`single`

`int8`

`uint8`

int16

int32

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2^0,0)

<data type expression>

Name of a data type object. For example, Simulink.NumericType.

Controlengineers.ir

## Product output data type

Select the product output data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

**Inherit: Inherit via internal rule (Default)**

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit: Inherit via back propagation**

Use data type of the driving block.

**Inherit: Same as input**

Use data type of input signal.

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2^0,0)

<data type expression>

Name of a data type object. For example, Simulink.NumericType.

Controlengineers.ir

## Summation output data type

Select the summation output data type of the sums **Sum**, **Sum D**, **Sum I1**, **SumI2**, and **SumI3**, which are sums computed internally within the block. To see where Simulink computes each of these sums, right-click the PID Controller block in your model and select **Look Under Mask**:

- **Sum** is the weighted sum of the proportional, derivative, and integral signals.
- **SumD** is the sum in the derivative filter feedback loop.
- **SumI1** is the sum of the block input signal (weighted by the integral gain I) and **SumI2**. **SumI1** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI2** is the difference between the weighted sum **Sum** and the limited block output. **SumI2** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI3** is the difference between the block output and the signal at the block's tracking input. **SumI3** is computed only when you select the **Enable tracking mode** box.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

**Inherit:** Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

---

**Note:** The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to **Inherit: Same as accumulator**.

---

**Inherit: Inherit via back propagation**

Use data type of the driving block.

**Inherit: Same as first input**

Use data type of first input signal.

**Inherit: Same as accumulator**

Use the same data type as the corresponding accumulator.

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as first input
- Same as accumulator

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via back propagation
- Same as input (default)

##### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Fixed-point data types.

##### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Mode

Select the category of accumulator data to specify

### Settings

**Default:** Inherit

#### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables a list of possible values:

- Inherit via internal rule (default)
- Same as first input

#### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Specifies fixed-point data types.

#### Expression

Specifies expressions that evaluate to data types. Selecting **Expression** enables you to enter an expression.

### Dependency

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data to be signed.

#### Unsigned

Specify the fixed-point data to be unsigned.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision, Binary point, Integer

#### Binary point

Specify binary point location.

#### Slope and bias

Enter slope and bias.

#### Best precision

Specify best-precision values. This option appears for some blocks.

#### Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0. This option appears for some blocks.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**
- **Bias**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that will hold the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependencies

Selecting **Mode** > **Fixed point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > Slope and bias for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Controlengineers.ir

## State name

Assign unique name to each state. The state names apply only to the selected block.

To assign a name to a single state, enter the name between quotes; for example, 'velocity'.

To assign names to multiple states, enter a comma-delimited list surrounded by braces; for example, {'a', 'b', 'c'}. Each name must be unique. To assign state names with a variable that has been defined in the MATLAB workspace, enter the variable without quotes. The variable can be a character vector, cell, or structure.

## Settings

**Default:** ' ' (no name)

## State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

### Settings

**Default:** Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

### Dependencies

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Command-Line Information

**Parameter:** StateMustResolveToSignalObject

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Code generation storage class

Select state storage class for code generation.

### Settings

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### *StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

### Dependencies

**State name** enables this parameter.

### Command-Line Information

Command-Line Information

**Parameter:** StateStorageClass

**Type:** character vector

**Value:** 'Auto' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

**Default:** 'Auto'

## TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

### Settings

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

### Dependency

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

### Command-Line Information

**Parameter Name:** `RTWStateStorageTypeQualifier`

**Value Type:** character vector

**Default:** ' ' (empty character vector)

## Characteristics

Direct Feedthrough	<p>The following ports support direct feedthrough:</p> <ul style="list-style-type: none"> <li>• Reset port</li> <li>• Integrator and filter initial condition port</li> <li>• Input port, for every integration method except Forward Euler</li> </ul>
Sample Time	Specified in the <b>Sample time</b> parameter

Scalar Expansion	Supported for gain parameters <b>P</b> , <b>I</b> , and <b>D</b> and for filter coefficient <b>N</b>
States	Inherited from driving block and parameters
Dimensionalized	Yes
Zero-Crossing Detection	Yes (in continuous-time domain)

# PID Controller (2 DOF) Discrete PID Controller (2 DOF)

Simulate continuous- or discrete-time two-degree-of-freedom PID controllers

## Library

Continuous, Discrete

## Description

Implement a continuous- or discrete-time two-degree-of-freedom controller (PID, PI, or PD) in your Simulink model. The PID Controller (2DOF) block allows you to implement setpoint weighting in your controller to achieve both smooth setpoint tracking and good disturbance rejection.

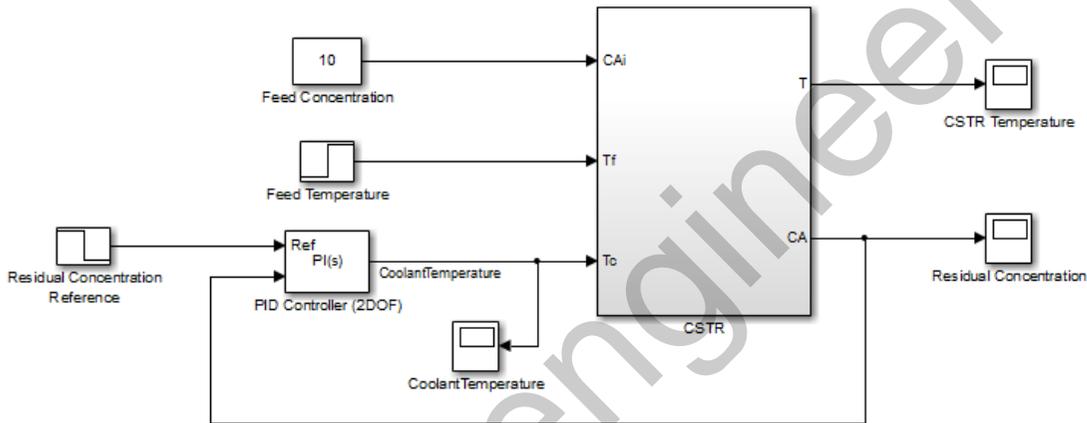

The PID Controller (2DOF) block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for each of the proportional, integral, and derivative actions according to the setpoint weights you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters. A first-order pole filters the derivative action. Controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software (**PID Tuner** or **Control System Designer**).

Configurable options in the PID Controller (2DOF) block include:

- Controller type (PID, PI, or PD)
- Controller form (Parallel or Ideal)
- Time domain (continuous or discrete)

- Initial conditions and reset trigger
- Output saturation limits and built-in anti-windup mechanism
- Signal tracking for bumpless control transfer and multiloop control

In one common implementation, the PID Controller (2DOF) block operates in the feedforward path of the feedback loop. The block receives a reference signal at the Ref input and a measured system output at the other input. For example:

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see the PID Controller block reference page.

You can generate code to implement your controller using any Simulink data type, including fixed-point data types. (Code generation requires Simulink Coder software; fixed-point implementation requires the Fixed-Point Designer product.)

For an example illustrating an application of the PID Controller (2 DOF) block, see the Simulink example Two Degree-of-Freedom PID Control for Setpoint Tracking.

## Data Type Support

The PID Controller (2DOF) block accepts real signals of any numeric data type that Simulink software supports, including fixed-point data types. See “Data Types Supported by Simulink” in the Simulink documentation for more information.

## Parameters

The following table summarizes the PID Controller (2DOF) block parameters, accessible via the block parameter dialog box.

Task	Parameters
Choose controller form and type.	<ul style="list-style-type: none"> <li>• <b>Controller Form</b> in Main tab</li> <li>• <b>Controller</b></li> </ul>
Choose discrete or continuous time.	<ul style="list-style-type: none"> <li>• <b>Time-domain</b></li> <li>• <b>Sample time</b></li> </ul>
Choose an integration method (discrete time).	<ul style="list-style-type: none"> <li>• <b>Integrator method</b></li> <li>• <b>Filter method</b></li> </ul>
Set and tune controller gains.	<ul style="list-style-type: none"> <li>• <b>Controller Parameters Source</b> in Main tab</li> <li>• <b>Proportional (P)</b> in Main tab</li> <li>• <b>Integral (I)</b> in Main tab</li> <li>• <b>Derivative (D)</b> in Main tab</li> <li>• <b>Filter coefficient (N)</b> in Main tab</li> <li>• <b>Use filtered derivative</b> in Main tab</li> <li>• <b>Setpoint weight (b)</b> in Main tab</li> <li>• <b>Setpoint weight (c)</b> in Main tab</li> </ul>
Set integrator and filter initial conditions.	<ul style="list-style-type: none"> <li>• <b>Initial conditions Source</b> in Main tab</li> <li>• <b>Integrator Initial condition</b> in Main tab</li> <li>• <b>Filter Initial condition</b> in Main tab</li> <li>• <b>Initial condition setting</b> (command line only)</li> <li>• <b>External reset</b> in Main tab</li> <li>• <b>Ignore reset when linearizing</b> in Main tab</li> </ul>
Limit block output.	<ul style="list-style-type: none"> <li>• <b>Limit output</b> in PID Advanced tab</li> <li>• <b>Lower saturation limit</b> in PID Advanced tab</li> </ul>

Task	Parameters
	<ul style="list-style-type: none"> <li>• <b>Upper saturation limit</b> in PID Advanced tab</li> <li>• <b>Ignore saturation when linearizing</b> in PID Advanced tab</li> </ul>
Configure anti-windup mechanism (when you limit block output).	<ul style="list-style-type: none"> <li>• <b>Anti-windup method</b> in PID Advanced tab</li> <li>• <b>Back-calculation gain (Kb)</b> in PID Advanced tab</li> </ul>
Enable signal tracking.	<ul style="list-style-type: none"> <li>• <b>Enable tracking mode</b> in PID Advanced tab</li> <li>• <b>Tracking gain (Kt)</b> in PID Advanced tab</li> </ul>
Configure data types.	<ul style="list-style-type: none"> <li>• <b>Parameter data type</b> in Data Type Attributes tab</li> <li>• <b>Product output data type</b> in Data Type Attributes tab</li> <li>• <b>Summation output data type</b> in Data Type Attributes tab</li> <li>• <b>Accumulator data type</b> in Data Type Attributes tab</li> <li>• <b>Integrator output data type</b> in Data Type Attributes tab</li> <li>• <b>Filter output data type</b> in Data Type Attributes tab</li> <li>• <b>Saturation output data type</b> in Data Type Attributes tab</li> <li>• <b>Lock output data type setting against changes by the fixed-point tools</b> in Data Type Attributes tab</li> <li>• <b>Saturate on integer overflow</b> in Data Type Attributes tab</li> <li>• <b>Integer rounding mode</b> in Data Type Attributes tab</li> </ul>

Task	Parameters
Configure block for code generation.	<ul style="list-style-type: none"> <li>• <b>State name</b> in State Attributes tab</li> <li>• <b>State name must resolve to Simulink signal object</b> in State Attributes tab</li> <li>• <b>Code generation storage class</b> in State Attributes tab</li> <li>• <b>Code generation storage type qualifier</b> in State Attributes tab</li> </ul>

Controlengineers.ir

## Controller form

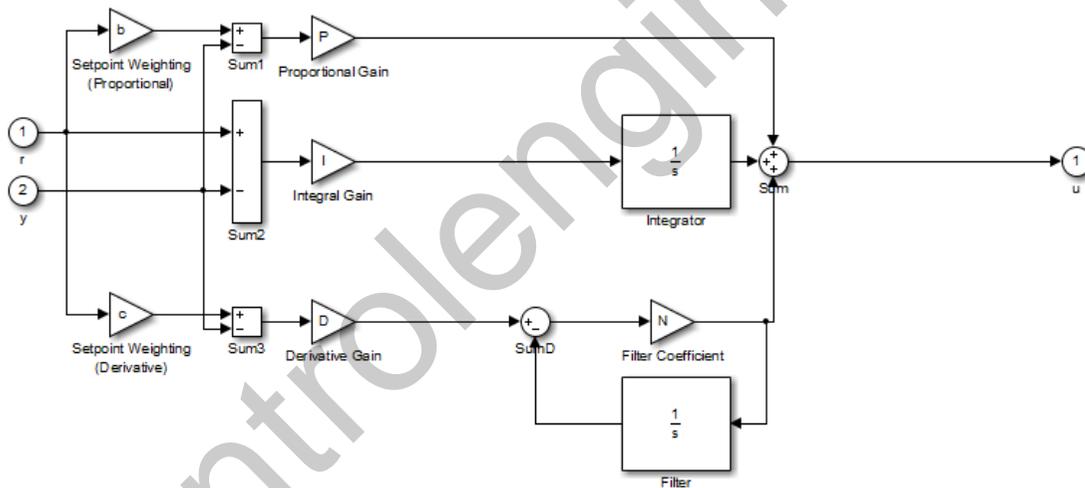

Select the controller form.

### Settings

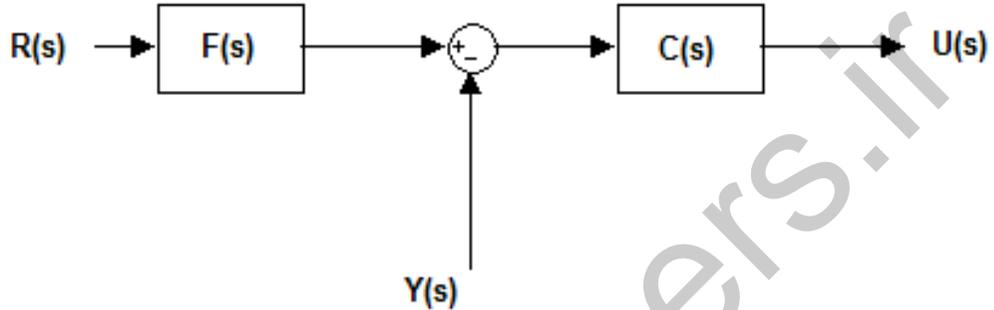

#### Parallel (Default)

Selects a controller form in which the proportional, integral, and derivative gains **P**, **I**, and **D** operate independently. The filter coefficient **N** sets the location of the pole in the derivative filter.

Parallel two-degree-of-freedom PID controller, where input 1 receives a reference signal and input 2 receives feedback from the measured system output:

The parallel two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram:

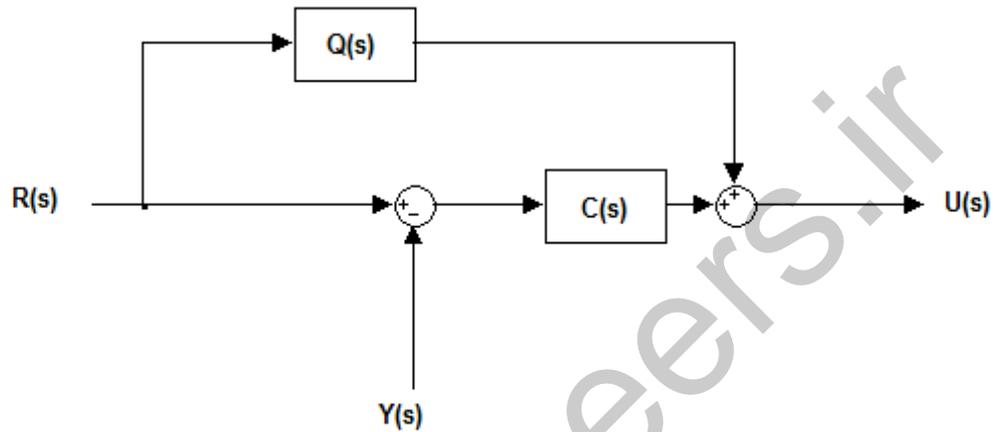

$R(s)$  represents the reference signal and  $Y(s)$  represents the feedback from measured system output. In this model,  $C(s)$  is a single degree-of-freedom controller, and  $F(s)$  acts as a prefilter on the reference signal. For a parallel two-degree-of-freedom PID controller in the **Continuous-time Time-domain**, the transfer functions  $F(s)$  and  $C(s)$  are:

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN}$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)}$$

where  $b$  and  $c$  are the **Setpoint weight** parameters.

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram:

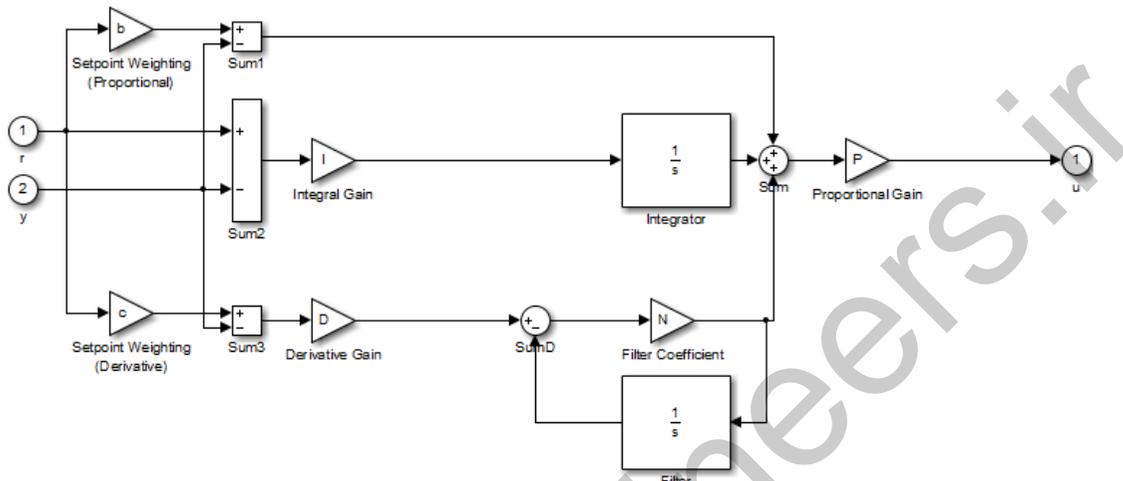

$R(s)$ ,  $Y(s)$ , and  $C(s)$  are as discussed previously. In this realization,  $Q(s)$  acts as feed-forward conditioning on the reference signal  $R(s)$ . For a parallel PID controller in the Continuous-time **Time-domain**, the transfer function  $Q(s)$  is:

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}$$

### Ideal

Selects a controller form in which the proportional gain  $P$  acts on the sum of all actions.

Ideal two-degree-of-freedom PID controller, where input 1 receives a reference signal and input 2 receives feedback from the measured system output:

Similarly to the parallel controller form discussed previously, the ideal two-degree-of-freedom PID controller can be modeled as a single degree-of-freedom controller  $C(s)$  with a prefilter  $F(s)$ . For an ideal two-degree-of-freedom PID controller in the Continuous-time **Time-domain**, the transfer functions  $F(s)$  and  $C(s)$  are:

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN}$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}$$

where **b** and **c** are the **Setpoint weight** parameters.

Alternatively, modeling the ideal two-degree-of-freedom PID controller as a one-degree-of-freedom controller  $C(s)$  with feed-forward conditioning  $Q(s)$  on the reference signal gives, in continuous-time:

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}$$

The controller transfer function for the current settings is displayed in the block dialog box.

## Controller

Specify the controller type.

### Settings

PID (Default)

Implements a controller with proportional, integral, and derivative action.

PI

Implements a controller with proportional and integral action.

PD

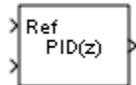

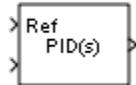

Implements a controller with proportional and derivative action.

The controller transfer function for the current settings is displayed in the block dialog box.

Controlengineers.ir

## Time-domain

Select continuous or discrete time domain. The appearance of the block changes to reflect your selection.

## Settings

### Continuous-time (Default)

Selects the continuous-time representation.

When the PID Controller (2DOF) block is in a model with synchronous state control (see the **State Control** block), you cannot select **Continuous-time**.

### Discrete-time

Selects the discrete-time representation. Selecting **Discrete-time** also allows you to specify the:

- **Sample time**, which is the discrete interval between samples.
- Discrete integration methods for the integrator and the derivative filter using the **Integrator method** and **Filter method** menus.

## Integrator method

(Available only when you set **Time-domain** to **Discrete-time**.) Specify the method used to compute the integrator output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

### Settings

#### Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the **Forward Euler** method can result in instability, even when discretizing a system that is stable in continuous time.

#### Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the **Backward Euler** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

If you activate the **Back-calculation Anti-windup method**, this integration method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

#### Trapezoidal

Selects the Bilinear approximation.

An advantage of the **Trapezoidal** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the **Trapezoidal** method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

If you activate the **Back-calculation Anti-windup method**, this integration method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a

model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

Controlengineers.ir

## Filter method

(Available only when you set **Time-domain** to **Discrete-time**.) Specify the method used to compute the derivative filter output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

### Settings

#### Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the **Forward Euler** method can result in instability, even when discretizing a system that is stable in continuous time.

#### Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the **Backward Euler** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value  $N > 0$  yields a stable result with this method.

This filter method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

#### Trapezoidal

Selects the Bilinear approximation.

An advantage of the **Trapezoidal** method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value  $N > 0$  yields a stable result with this method. Of all available filter methods, the **Trapezoidal** method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

This filter method can cause algebraic loops in your controller. Algebraic loops can slow down simulation of the model. In addition, if you want to generate code

using Simulink Coder software or the Fixed-Point Designer product, you cannot generate code for a model that contains an algebraic loop. For more information about algebraic loops in Simulink models, see “Algebraic Loops” in the Simulink documentation.

Controlengineers.ir

## Sample time (-1 for inherited)

(Available only when you set **Time-domain** to Discrete-time.) Specify the discrete interval between samples.

### Settings

**Default:** 1

By default, the block uses a discrete sample time of 1. To specify a different sample time, enter another discrete value, such as 0.1.

If you specify a value of  $-1$ , the PID Controller (2DOF) block inherits the sample time from upstream blocks. Do not enter a value of 0; to implement a continuous-time controller, select the **Time-domain Continuous-time**.

See “Specify Sample Time” in the online documentation for more information.

Controlengineers.ir

## Controller Parameters Source

Select the source of the controller gains, filter coefficient, and setpoint weights. You can provide these parameters explicitly in the block dialog box, or enable external inputs for them on the block. Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control, in which controller gains are determined by logic or other calculation in the Simulink model and passed to the block.

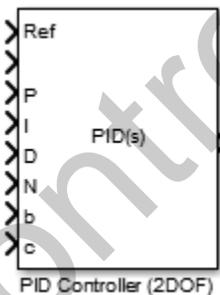

### Settings

internal (Default)

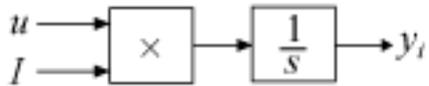

Specify the PID gains and filter coefficient explicitly using the **P**, **I**, **D**, **N**, **b**, and **c** parameters.

external

Specify the PID gains and filter coefficient externally. An additional input port appears under the block input for each parameter that is required for the current controller type:

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because of the way the PID gains are implemented within the block. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the signal to be integrated is multiplied by the externally-supplied integrator gain,  $I$ , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain  $D$  to be differentiated.

Controlengineers.ir

## Proportional (P)

Specify the proportional gain  $P$ .

**Default:** 1

Enter a finite, real gain value into the **Proportional (P)** field. Use either scalar or vector gain values. For a **parallel PID Controller form**, the proportional action is independent of the integral and derivative actions. For an **ideal PID Controller form**, the proportional action acts on the integral and derivative actions. See “Controller form” on page 1-1248 for more information about the role of  $P$  in the controller transfer function.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

Controlengineers.ir

## Integral (I)

(Available for PID and PI controllers.) Specify the integral gain  $I$ .

**Default:** 1

Enter a finite, real gain value into the **Integral (I)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

Controlengineers.ir

## Derivative (D)

(Available for PID and PD controllers.) Specify the derivative gain D.

**Default:** 0

Enter a finite, real gain value into the **Derivative (D)** field. Use either scalar or vector gain values.

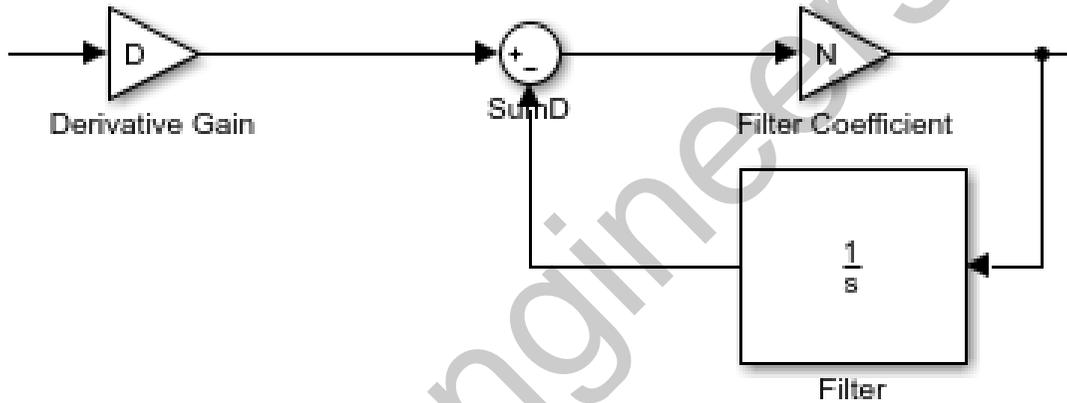

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design).

Controlengineers.ir

## Filter coefficient (N)

Specifies the filter coefficient of the controller.

(Available for PID and PD controllers, when **Use filtered derivative** is checked.)  
 Specify the filter coefficient N, which determines the pole location of the filter in the derivative action:

The filter pole falls at  $s = -N$  in the **Continuous-time Time-domain**. For **Discrete-time**, the location of the pole depends on which **Filter method** you select (for sampling time  $T_s$ ):

- Forward Euler:

$$z_{pole} = 1 - NT_s$$

- Backward Euler:

$$z_{pole} = \frac{1}{1 + NT_s}$$

- Trapezoidal:

$$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$$

**Default:** 100.

Enter a finite, real gain value into the **Filter Coefficient (N)** field. Use either scalar or vector gain values. Note that the PID controller (2DOF) block does not support  $N = \text{inf}$  (ideal unfiltered derivative).

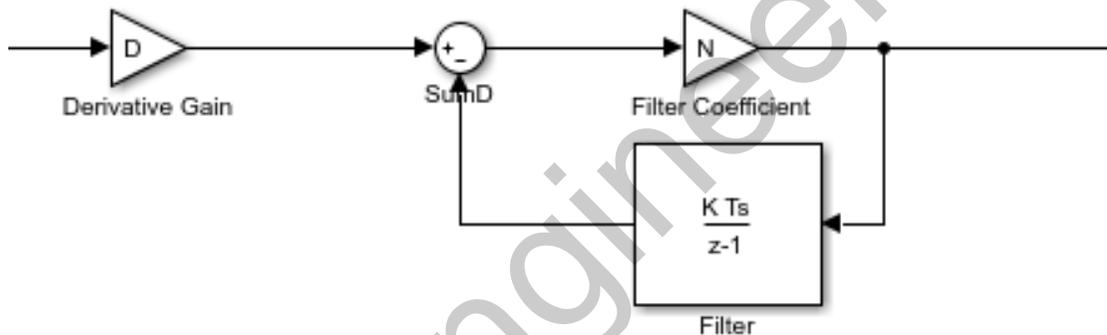

When you have Simulink Control Design software installed, you can automatically tune the controller gains using the **PID Tuner** or **Control System Designer**. See “Choosing a Control Design Approach” (Simulink Control Design). Automatic tuning requires  $N > 0$ .

Controlengineers.ir

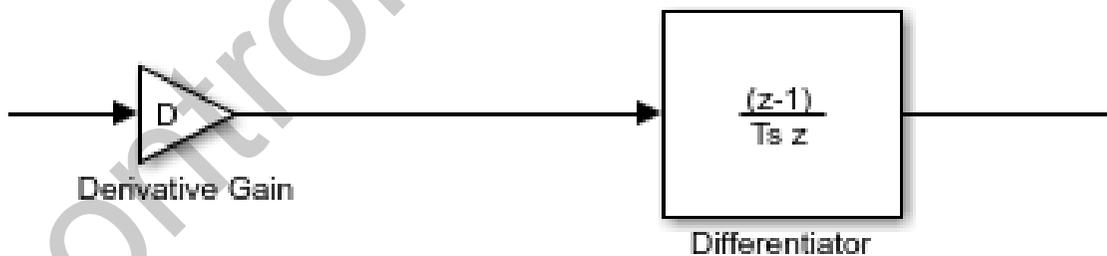

## Use Filtered Derivative

Specify whether derivative term is filtered (finite N) or unfiltered. Unfiltered derivative is available only for discrete-time controllers.

Unchecking this option replaces the filtered derivative with a discrete differentiator. For example, if **Filter Method** is Forward Euler, then the filtered derivative term is represented by:

When you uncheck **Use filtered derivative**, the derivative term becomes:

### Settings

- On (Default)  
Use derivative filter (finite N).

Off

Derivative is unfiltered.

controlengineers.ir

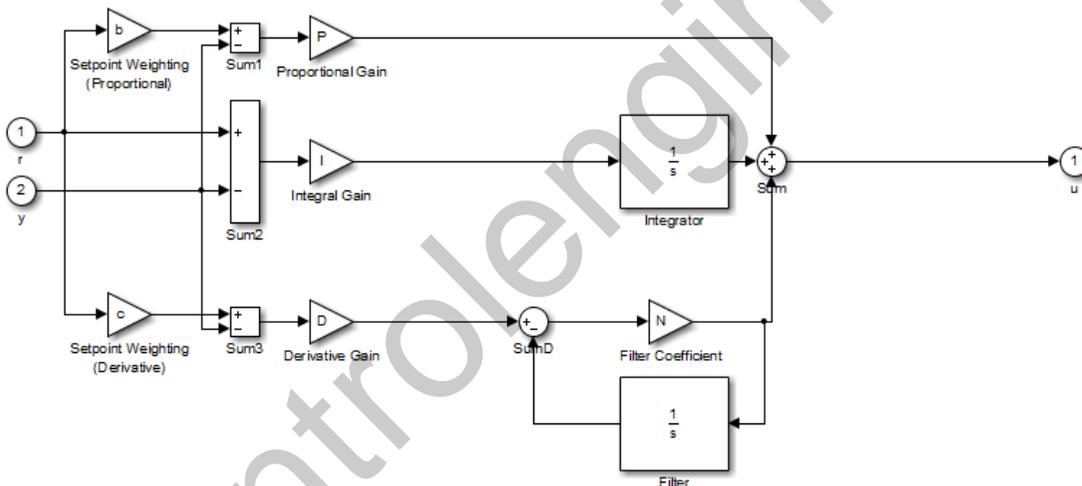

## Setpoint weight (b)

Specify the proportional setpoint weight b.

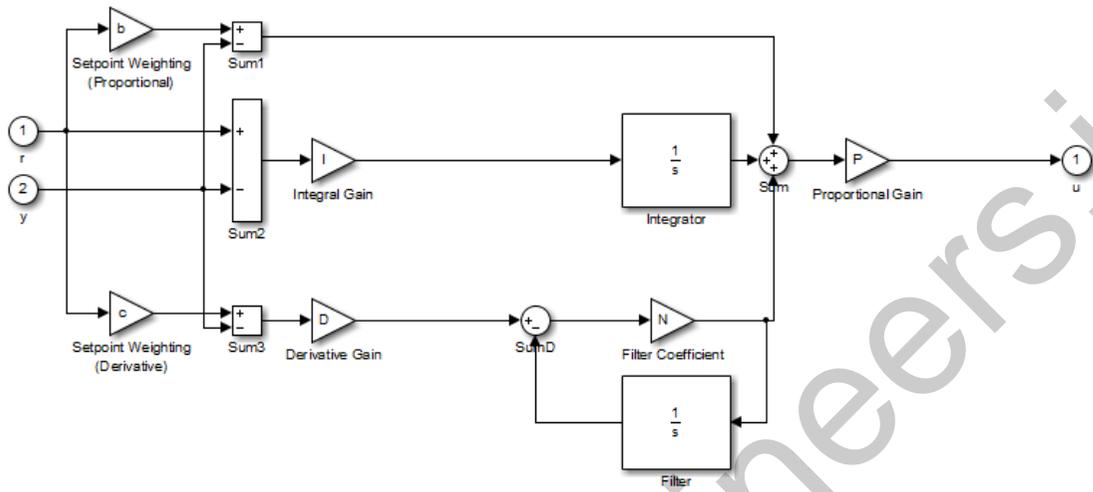

**Default:** 1

Enter the proportional setpoint weight value into the **Setpoint weight (b)** field. Setting  $b = 0$  eliminates the proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint.

The following diagrams show the role of **Setpoint weight (b)** in PID controllers of Parallel and Ideal form. See “Controller form” on page 1-1248 for a discussion of the corresponding transfer functions.

Parallel Two-Degree-of-Freedom PID Controller

**Ideal Two-Degree-of-Freedom PID Controller**

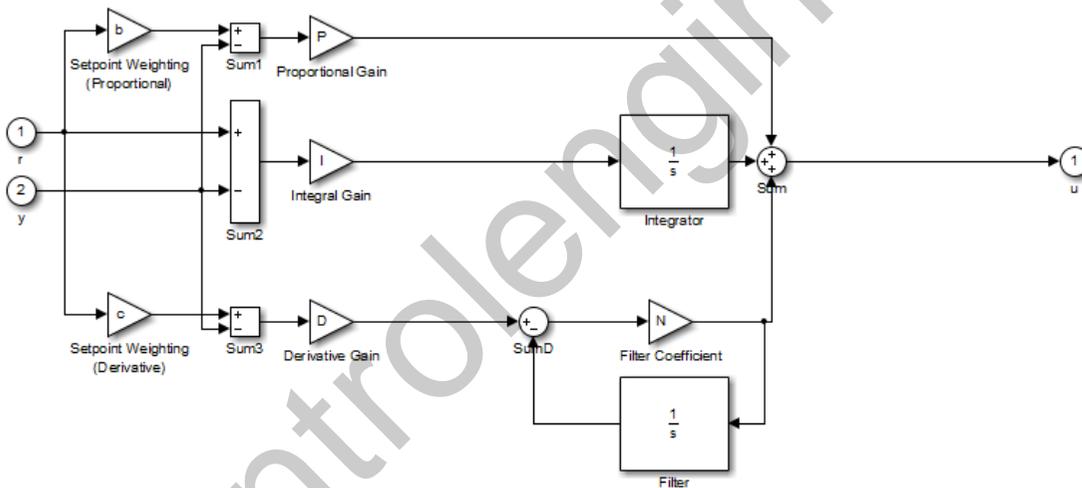

Controlengineers.ir

## Setpoint weight (c)

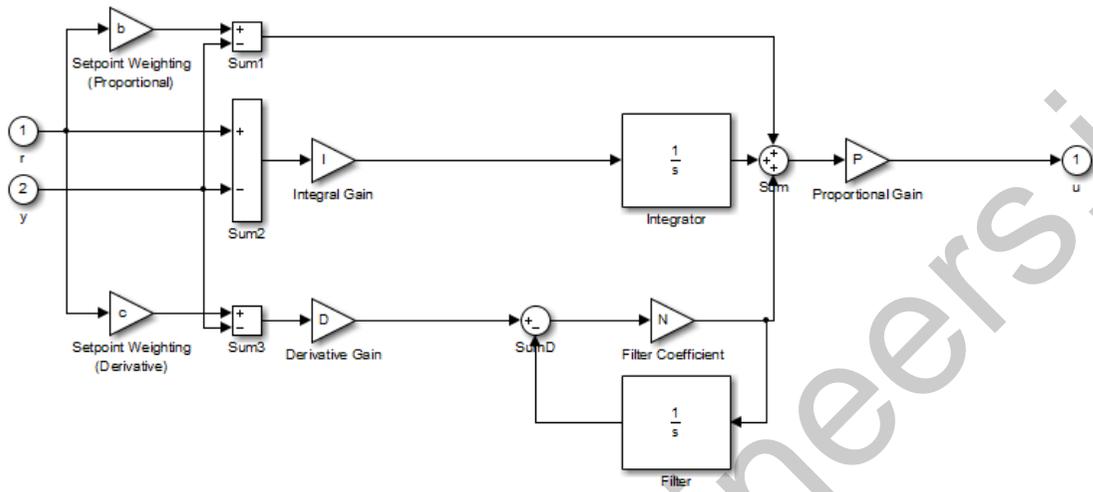

(Available for PID and PD controllers.) Specify the derivative setpoint weight  $c$ .

Enter the derivative setpoint weight value into the **Setpoint weight (c)** field. To implement a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response, set  $c = 0$ . Setting  $c = 0$  yields a controller with derivative action on the measured system response but not on the reference input.

The following diagrams show the role of **Setpoint weight (c)** in Parallel and Ideal PID controllers. See “Controller form” on page 1-1248 for a discussion of the corresponding transfer functions.

Parallel Two-Degree-of-Freedom PID Controller

**Ideal Two-Degree-of-Freedom PID Controller**

Controlengineers.ir

## Initial conditions Source

Select the source of the integrator and filter initial conditions. Simulink uses initial conditions to initialize the integrator and filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1276). The integrator and filter initial conditions in turn determine the initial block output.

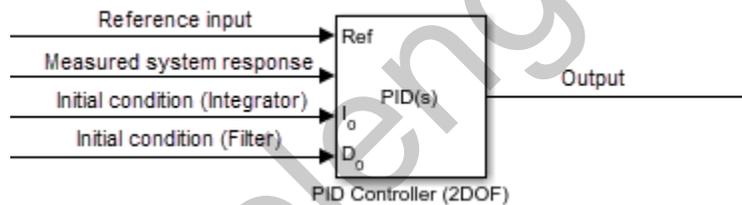

### Settings

internal (Default)

Specifies the integrator and filter initial conditions explicitly using the **Integrator Initial condition** and **Filter Initial condition** parameters.

external

Specifies the integrator and filter initial conditions externally. An additional input port appears under the block inputs for each initial condition:  $I_0$  for the integrator and  $D_0$  for the filter:

## Integrator Initial condition

(Available only when **Initial conditions Source** is **internal** and the controller includes integral action.) Specify the integrator initial value. Simulink uses the initial condition to initialize the integrator output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1276). The integrator initial condition, together with the filter initial condition, determines the initial output of the PID Controller (2DOF) block.

**Default:** 0

Simulink does not permit the integrator initial condition to be `inf` or `NaN`.

Controlengineers

## Filter Initial condition

(Available only when **Initial conditions Source** is **internal**, the controller includes derivative action, and **Use filtered derivative** is checked.) Specify the filter initial value. Simulink uses the initial condition to initialize the filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1276). The filter initial condition, together with the integrator initial condition, determines the initial output of the PID Controller (2DOF) block.

**Default:** 0

Simulink does not permit the filter initial condition to be `inf` or `NaN`.

Controlengineers.ir

## Initial condition setting

Specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. This parameter can be changed only at the command line using `set_param` to set the `InitialConditionSetting` parameter of the block.

### Settings

State (most efficient) (Default)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

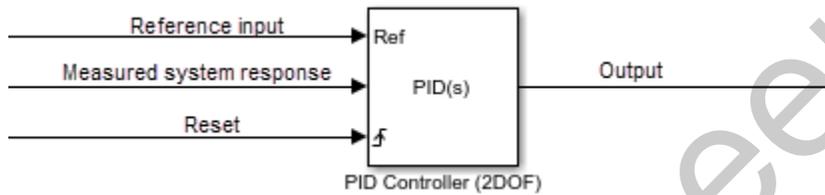

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

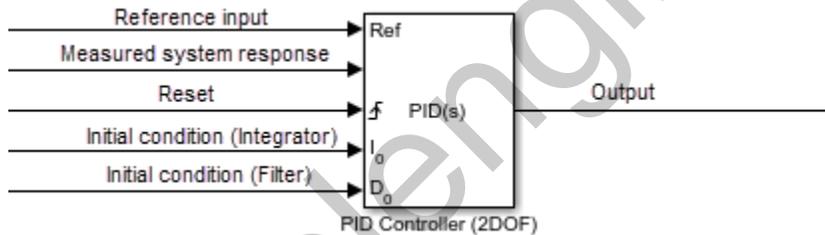

For more information about the **Initial condition setting** parameters, see the Discrete-Time Integrator block.

## External reset

Select the trigger event that resets the integrator and filter outputs to the initial conditions you specify in the **Integrator Initial condition** and **Filter Initial condition** fields. Selecting any option other than none enables a reset input on the block for the external reset signal, as shown:

Or, if the **Initial conditions Source** is External:

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

---

**Note:** To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller (2DOF) block.

---

### Settings

none (Default)

Does not reset the integrator and filter outputs to initial conditions.

rising

Resets the outputs when the reset signal has a rising edge.

falling

Resets the outputs when the reset signal has a falling edge.

either

Resets the outputs when the reset signal either rises or falls.

level

Resets and holds the outputs to the initial conditions while the reset signal is nonzero.

Controlengineers.ir

## Ignore reset when linearizing

Force Simulink linearization commands to ignore any reset mechanism that you have chosen with the **External reset** menu. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the PID Controller (2DOF) block to reset.

### Settings

- Off (Default)  
Simulink linearization commands do not ignore states corresponding to the reset mechanism.
- On  
Simulink linearization commands ignore states corresponding to the reset mechanism.

Controlengineers.ir

## Enable zero-crossing detection

Enable zero-crossing detection in continuous-time models upon reset and upon entering or leaving a saturation state.

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate an **External reset** in your PID Controller (2DOF) block, activating zero-crossing detection can reduce computation time in your simulation. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

On (Default)

Uses zero-crossing detection at any of the following events: reset; entering or leaving an upper saturation state; and entering or leaving a lower saturation state.

Off

Does not use zero-crossing detection.

Enabling zero-crossing detection for the PID Controller (2DOF) block also enables zero-crossing detection for all under-mask blocks that include the zero-crossing detection feature.

## Limit output

Limit the block output to values you specify as the **Lower saturation limit** and **Upper saturation limit** parameters.

Activating this option limits the block output internally to the block, obviating the need for a separate Saturation on page 1-1491 block after the controller in your Simulink model. It also allows you to activate the built-in anti-windup mechanism (see “Anti-windup method” on page 1-1283).

### Settings

Off (Default)

Does not limit the block output, which is the weighted sum of the proportional, integral, and derivative actions.

On

Limits the block output to the **Lower saturation limit** or the **Upper saturation limit** whenever the weighted sum exceeds those limits. Allows you to select an **Anti-windup method**.

## Lower saturation limit

(Available only when you select the **Limit Output** box.) Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

**Default:** -inf

Controlengineers.ir

## Upper saturation limit

(Available only when you select the **Limit Output** box.) Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

**Default:** inf

controlengineers.ir

## Anti-windup method

(Available only when you select the **Limit Output** option and the controller includes integral action.) Select an anti-windup mechanism to discharge the integrator when the block is saturated, which occurs when the sum of the block components exceeds the output limits.

When you select the **Limit output** check box and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator wind-up), increasing the difference between the block output and the sum of the block components. Without a mechanism to prevent integrator wind-up, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to discharge the integrator and return the weighted sum within the block saturation limit.

In both cases, controller performance can suffer. To combat the effects of wind-up without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. Activating an anti-windup mechanism can improve controller performance.

### Settings

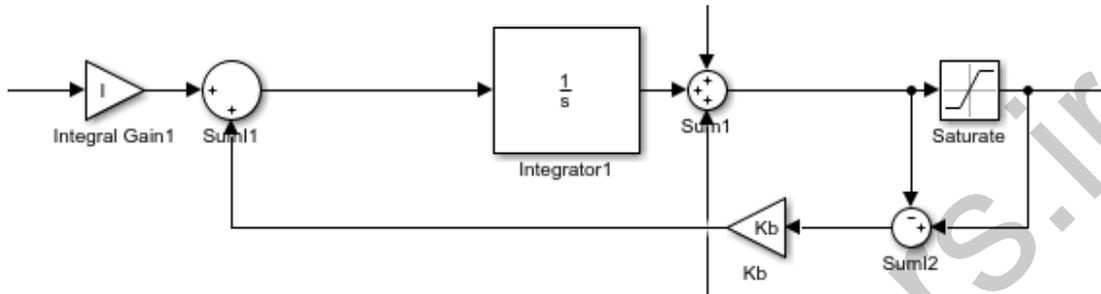

none (Default)

Does not use an anti-windup mechanism. This setting can cause the block's internal signals to be unbounded even if the output appears to be bounded by the saturation limits. This can result in slow recovery from saturation or unexpected overflows.

back-calculation

Discharges the integrator when the block output saturates using the integral-gain feedback loop:

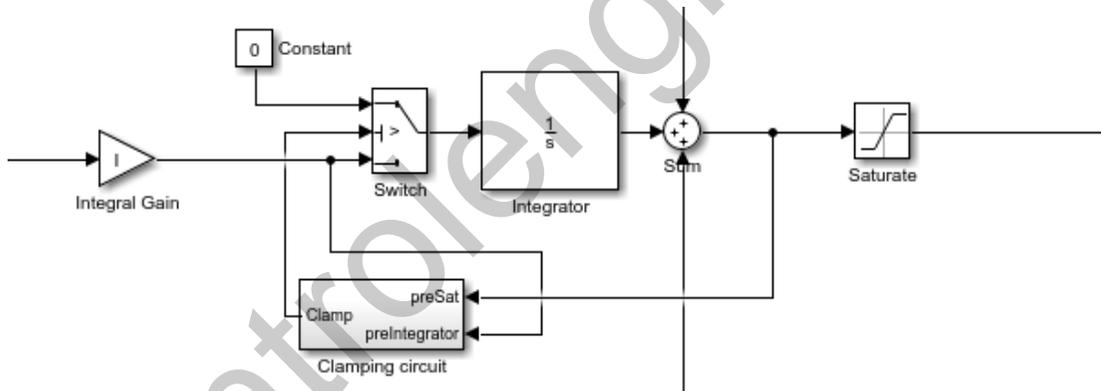

1 Blocks – Alphabetical List

You can also specify a value for the **Back-calculation coefficient (Kb)**.

clamping

Stops integration when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Resumes integration when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. The integrator portion of the block is:

The clamping circuit implements the logic necessary to determine whether integration continues.

## Back-calculation gain (Kb)

(Available only when the back-calculation **Anti-windup method** is active.) Specify the gain coefficient of the anti-windup feedback loop.

The back-calculation anti-windup method discharges the integrator on block saturation using a feedback loop having gain coefficient Kb.

**Default:** 1

Controlengineers.ir

## Ignore saturation when linearizing

Force Simulink linearization commands ignore PID Controller (2DOF) block output limits. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the PID Controller (2DOF) block to exceed the output limits.

### Settings

On (Default)

Simulink linearization commands ignore states corresponding to saturation.

Off

Simulink linearization commands do not ignore states corresponding to saturation.

Controlengineers.ir

## Enable tracking mode

(Available for any controller with integral action.) Activate signal tracking, which lets the output of the PID Controller (2DOF) block follow a tracking signal. Provide the tracking signal to the block at the TR port, which becomes active when you select **Enable tracking mode**.

When signal tracking is active, the difference between the tracked signal and the block output is fed back to the integrator input with a gain  $K_t$ . You can also specify the value of the **Tracking coefficient (Kt)**.

For information about using tracking mode to implement bumpless control transfer scenarios and multiloop controllers, see “Enable tracking mode” on page 1-1196 in the PID Controller reference page.

### Settings

- Off (Default)  
Disables signal tracking and removes TR block input.
- On  
Enables signal tracking and activates TR input.

## Tracking gain (Kt)

(Available only when you select **Enable tracking mode**.) Specify Kt, which is the gain of the signal tracking feedback loop.

**Default:** 1

controlengineers.ir

## Parameter data type

Select the data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt** and the setpoint weighting parameters **b** and **c**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

**Inherit:** Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**Inherit:** Same as input

Use data type of input signal.

Name of a data type object. For example, Simulink.NumericType.

Controlengineers.ir

## Product output data type

Select the product output data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt** and the setpoint weighting parameters **b** and **c**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

**Inherit:** Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**Inherit:** Same as input

Use data type of input signal.

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2^0,0)

<data type expression>

Name of a data type object. For example, Simulink.NumericType.

Controlengineers.ir

## Summation output data type

Select the summation output data type of the sums **Sum**, **Sum1**, **Sum2**, **Sum3**, **Sum D**, **Sum I1**, **SumI2**, and **SumI3**, which are sums computed internally within the block. To see where Simulink computes each of these sums, right-click the PID Controller (2DOF) block in your model and select **Look Under Mask**:

- **Sum** is the weighted sum of the proportional, derivative, and integral signals.
- **Sum1** is the difference between the reference input weighted by **b** and the measured system response.
- **Sum2** is the difference between the reference input weighted by **c** and the measured system response.
- **Sum3** is the difference between the unweighted reference input and the measured system response.
- **SumD** is the sum in the derivative filter feedback loop.
- **SumI1** is the sum of the block input signal (weighted by the integral gain **I**) and **SumI2**. **SumI1** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI2** is the difference between the weighted sum **Sum** and the limited block output. **SumI2** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI3** is the difference between the block output and the signal at the block's tracking input. **SumI3** is computed only when you select the **Enable tracking mode** box.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

### Settings

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

---

**Note:** The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to **Inherit: Same as accumulator**.

---

**Inherit: Inherit via back propagation**

Use data type of the driving block.

**Inherit: Same as first input**

Use data type of first input signal.

**Inherit: Same as accumulator**

Use the same data type as the corresponding accumulator.

## Accumulator data type

Specify the accumulator data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Use internal rule to determine accumulator data type.

**Inherit:** Same as first input

Use data type of first input signal.

**double**

Accumulator data type is double.

**single**

Accumulator data type is single.

**int8**

Accumulator data type is int8.

**uint8**

Accumulator data type is uint8.

**int16**

Accumulator data type is int16.

**uint16**

Accumulator data type is uint16.

**int32**

Accumulator data type is int32.

**uint32**

Accumulator data type is uint32.

**fixdt(1,16,0)**

Accumulator data type is fixed point fixdt(1,16,0).

**fixdt(1,16,2^0,0)**

Accumulator data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as first input
- Same as accumulator

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via back propagation
- Same as input (default)

##### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Fixed-point data types.

##### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Mode

Select the category of accumulator data to specify

### Settings

**Default:** Inherit

#### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables a list of possible values:

- Inherit via internal rule (default)
- Same as first input

#### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Specifies fixed-point data types.

#### Expression

Specifies expressions that evaluate to data types. Selecting **Expression** enables you to enter an expression.

### Dependency

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data to be signed.

#### Unsigned

Specify the fixed-point data to be unsigned.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision, Binary point, Integer

#### Binary point

Specify binary point location.

#### Slope and bias

Enter slope and bias.

#### Best precision

Specify best-precision values. This option appears for some blocks.

#### Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0. This option appears for some blocks.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**
- **Bias**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that will hold the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependencies

Selecting **Mode** > **Fixed point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > Slope and bias enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## State name

Assign unique name to each state. The state names apply only to the selected block.

To assign a name to a single state, enter the name between quotes; for example, 'velocity'.

To assign names to multiple states, enter a comma-delimited list surrounded by braces; for example, {'a', 'b', 'c'}. Each name must be unique. To assign state names with a variable that has been defined in the MATLAB workspace, enter the variable without quotes. The variable can be a character vector, cell, or structure.

### Settings

Default: ' ' (no name)

## State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

### Settings

Default: Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

### Dependencies

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Command-Line Information

**Parameter:** StateMustResolveToSignalObject

**Type:** character vector

**Value:** 'off' | 'on'

Default: 'off'

controlengineers.ir

## Code generation storage class

Select state storage class for code generation.

### Settings

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

### Dependencies

**State name** enables this parameter.

### Command-Line Information

Command-Line Information

**Parameter:** StateStorageClass

**Type:** character vector

**Value:** 'Auto' | 'ExportedGlobal' | 'ImportedExtern' |  
'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

**Default:** 'Auto'

## TypeQualifier

---

**Note:** **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

### Settings

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

### Dependency

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

### Command-Line Information

**Parameter Name:** `RTWStateStorageTypeQualifier`

**Value Type:** character vector

**Default:** ' ' (empty character vector)

## Characteristics

Direct Feedthrough	The following ports support direct feedthrough: <ul style="list-style-type: none"> <li>• Reset port</li> <li>• Integrator and filter initial condition port</li> <li>• Input port, for every integration method except Forward Euler</li> </ul>
Sample Time	Specified in the <b>Sample time</b> parameter

Scalar Expansion	Supported for gain parameters <b>P</b> , <b>I</b> , and <b>D</b> and for filter coefficient <b>N</b> , and for setpoint weights <b>b</b> and <b>c</b>
States	Inherited from driving block and parameters
Dimensionalized	Yes
Zero-Crossing Detection	Yes (in continuous-time domain)

## See Also

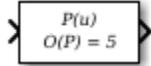

### See Also

Derivative | Discrete Derivative | Discrete-Time Integrator | Gain | Integrator | PID Controller

Introduced in R2009b

# Polynomial

Perform evaluation of polynomial coefficients on input values

## Library

Math Operations

## Description

You define a set of polynomial coefficients in the form that the MATLAB `polyval` command accepts. The block evaluates  $P(u)$  at each time step for the input  $u$ . The inputs and coefficients must be real.

## Data Type Support

The Polynomial block accepts real signals of type `double` or `single`. The **Polynomial coefficients** parameter must be of the same type as the inputs. The output data type is the same as the input data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Polynomial coefficients

Specify polynomial coefficients in MATLAB `polyval` form. The first coefficient corresponds to  $x^N$  and the remaining coefficients correspond to decreasing orders of  $x$ . The last coefficient represents the constant for the polynomial. See `polyval` in the MATLAB documentation for more information.

## Examples

The `sldemo_boiler` model shows how to use the Polynomial block.

In the Boiler Plant model/digital thermometer subsystem, the Polynomial block models a first-order polynomial using the coefficients [0.05 0.75]:

This subsystem models a digital thermometer composed of a simple temperature sensor and an ADC. The transfer function of the sensor is:  
 $V = .05 * T + 0.75$   
 for T in degrees C.

The conversion block inverts the combined transfer function of the sensor and ADC so that the output is an `sfix(8)` code representing T in degrees C.

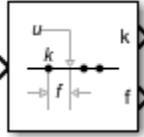

## Characteristics

Data Types	Double   Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Prelookup

Compute index and fraction for Interpolation Using Prelookup block

## Library

Lookup Tables

## Description

The Prelookup block calculates the index and interval fraction that specify how its input value  $u$  relates to the breakpoint dataset. The Prelookup block works best with the Interpolation Using Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an  $n$ -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n-D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility and more efficient simulation and code generation than the n-D Lookup Table block. For more information, see “Efficiency of Performance”.

## Supported Block Operations

To use the Prelookup block, you specify a set of breakpoint values directly on the dialog box or feed values into the `bp` input port. Typically, this breakpoint data set corresponds to one dimension of the table data in an Interpolation Using Prelookup block. The Prelookup block generates a pair of outputs for each input value  $u$  by calculating:

- The index of the breakpoint set element that is less than or equal to  $u$  and forms an interval containing  $u$
- The interval fraction in the range  $0 \leq f < 1$ , representing the normalized position of  $u$  on the breakpoint interval between the index and the next index value for in-range input

For example, if the breakpoint data set is [0 5 10 20 50 100] and the input value  $u$  is 55, the index is 4 and the fractional value is 0.1. Labels for the index and interval fraction appear as  $k$  and  $f$  on the Prelookup block icon. The index value is zero based.

The interval fraction can be negative or greater than 1 for out-of-range input. See the documentation for the **Extrapolation method** block parameter for more information.

## Data Type Support

The Prelookup block accepts real signals of numeric data types that Simulink supports, except Boolean. The Prelookup block supports fixed-point data types for signals and breakpoint data. You can also use a bus object as the output data type, which can help to simplify a model.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Main Tab” on page 1-1335
- “Data Types Tab” on page 1-1342

## Main Tab

### Specification

Specify whether to enter data as explicit breakpoints, as parameters that generate evenly spaced breakpoints, or via a breakpoint object. If you set this parameter to:

- **Explicit values**, the **Source** and **Value** parameters are visible on the dialog box.
- **Even spacing**, the **First point**, **Spacing**, and **Number of points** parameters are visible on the dialog box.
- **Breakpoint object**, the **Name** parameter is visible on the dialog box.

### Source

Specify whether to enter breakpoint data in the dialog box or to inherit the data from an input port. This parameter is available when **Specification** is set to **Explicit values**. If you set **Source** to:

- **Dialog**, enter breakpoint data in the text box under **Value**.
- **Input port**, verify that an upstream signal supplies breakpoint data to the **bp** input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes from the **bp** input port.

### Value

If you set:

- **Specification** to **Explicit values** and **Source** to **Dialog**, explicitly specify the breakpoint data. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify breakpoint attributes on the **Data Types** pane. This parameter is available when **Source** is set to **Dialog**.
- **Source** to **Input port**, verify that an upstream signal supplies table data to the **bp** input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify breakpoint attributes on the **Data Types** pane. This parameter is available when **Source** is set to **Dialog**.

Click **Edit** to open the Lookup Table Editor (see “Edit Lookup Tables” in the Simulink documentation).

### First point

Specify the first point in your evenly spaced breakpoint data. To enable this parameter, set **Specification** to **Even spacing**.

### Spacing

Specify the spacing between points in your evenly spaced breakpoint data. To enable this parameter, set **Specification** to **Even spacing**.

### Number of points

Specify the number of evenly spaced points in your breakpoint data. To enable this parameter, set **Specification** to **Even spacing**.

### Name

If you set **Specification** to **Breakpoint object**, specify the name of an existing Simulink.Breakpoint object. An existing breakpoint object already contains breakpoint data.

### Index search method

Select Evenly spaced points, Linear search, or Binary search. Each search method has speed advantages in different situations:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting **Evenly spaced points** to calculate table indices. This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.
- For unevenly spaced breakpoint sets, follow these guidelines:
  - If input values for  $u$  do not vary significantly between time steps, selecting **Linear search** with **Begin index search using previous index result** produces the best performance.
  - If input values for  $u$  jump more than one or two table intervals per time step, selecting **Binary search** produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

---

**Note:** The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
  - The index search method is **Evenly spaced points**.
- 

### Output selection

Specify the signals (index, fraction, or both) that the block outputs. If you want the block to output the index and interval fraction, you can have it output either individual signals or a bus signal that includes both the index and fraction signals.

- **Index only** outputs just the index, without the fraction. Typical applications for this option include:
  - Feeding a Direct Lookup Table (n-D) block, with no interpolation on the interval
  - Feeding selection ports of a subtable selection for an Interpolation Using Prelookup block
  - Performing nonlinear quantizations

- Index and fraction outputs the index and fraction as individual signals.
- Index and fraction as bus outputs a bus signal that includes the index and fraction signals. Using a bus for these signals:
  - Simplifies the model by tying these two related signals together.
  - Creates a testpoint `DpResult` structure for the AUTOSAR 4.0 library.
  - For the AUTOSAR 4.0 library, avoids the creation of extra copies during code generation when the Prelookup and Interpolation Using Prelookup blocks are in separate models.

---

**Note:** Selecting Index and fraction as bus displays the **Output** parameter in the **Data Types** pane and sets the **Output** parameter to **Inherit: auto**. Change this default value to specify a user-defined bus object. For details about defining the bus object, see the **Output** parameter description.

---

### Begin index search using previous index result

Select this check box when you want the block to start its search using the index found at the previous time step. For input values of  $u$  that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

### Extrapolation method

Specify how to handle out-of-range values for the block input  $u$ . Options include:

- Clip

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> <li>• Index of the first breakpoint (for example, 0)</li> <li>• Interval fraction of 0</li> </ul>
Greater than the last breakpoint	<ul style="list-style-type: none"> <li>• Index of the next-to-last breakpoint</li> <li>• Interval fraction of 1</li> </ul>

Suppose the range is [ 1 2 3 ] and you select this option. If  $u$  is 0.5, the index is 0 and the interval fraction is 0. If  $u$  is 3.5, the index is 1 and the interval fraction is 1.

- Linear

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> <li>• Index of the first breakpoint (for example, 0)</li> <li>• Interval fraction that represents the linear distance from <math>u</math> to the first breakpoint</li> </ul>
Greater than the last breakpoint	<ul style="list-style-type: none"> <li>• Index of the next-to-last breakpoint</li> <li>• Interval fraction that represents the linear distance from the next-to-last breakpoint to <math>u</math></li> </ul>

Suppose the range is [ 1 2 3 ] and you select this option. If  $u$  is 0.5, the index is 0 and the interval fraction is -0.5. If  $u$  is 3.5, the index is 1 and the interval fraction is 1.5.

---

**Note:** The Prelookup block supports linear extrapolation only when all of these conditions apply:

- The input  $u$ , breakpoint data, and fraction output use floating-point data types.
  - The index uses a built-in integer data type.
- 

### Use last breakpoint for input at or above upper limit

Specify how to index input values of  $u$  that are greater than or equal to the last breakpoint. The index value is zero-based. When input equals the last breakpoint, block outputs differ as follows:

Check Box	Block Outputs
Selected	<ul style="list-style-type: none"> <li>• Index of the last element in the breakpoint data set</li> <li>• Interval fraction of 0</li> </ul>
Cleared	<ul style="list-style-type: none"> <li>• Index of the next-to-last breakpoint</li> <li>• Interval fraction of 1</li> </ul>

This check box is visible only when:

- **Output only the index** is cleared.
- **Extrapolation method** is **Clip**.

However, when **Output only the index** is selected and **Extrapolation method** is **Clip**, the block behaves as if this check box is selected even though it is invisible.

---

**Tip:** When you select **Use last breakpoint for input at or above upper limit** for a Prelookup block, you must also select **Valid index input may reach last index** for the Interpolation Using Prelookup block to which it connects. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

---

#### Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input  $u$  is out of range. Options include:

- **None** — Simulink software takes no action.
- **Warning** — Simulink software displays a warning and continues the simulation.
- **Error** — Simulink software terminates the simulation and displays an error.

#### Remove protection against out-of-range input in generated code

Specify whether or not to include code that checks for out-of-range breakpoint inputs.

Check Box	Result	When to Use
Selected	<p>Generated code does not include conditional statements to check for out-of-range breakpoint inputs.</p> <p>When the input <math>k</math> or <math>f</math> is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.</p>	For code efficiency

Check Box	Result	When to Use
Cleared	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

---

**Note:** When you select the **Remove protection against out-of-range index in generated code** check box and the input  $k$  or  $f$  is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

---

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code
- By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

**Sample time**

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Data Types Tab

---

**Note:** The parameters for breakpoint attributes (data type, minimum, and maximum) are not available when you set **Source** to **Input** port. In this case, the block inherits all breakpoint attributes from the **bp** input port.

---

### Breakpoint > Data Type

Specify the breakpoint data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the breakpoint data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

---

**Tip:** Specify a breakpoint data type different from the data type of input `u` for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal `u`
  - Sharing of prescaled breakpoint data between two Prelookup blocks with different data types for input `u`
  - Sharing of custom storage breakpoint data in the generated code for blocks with different data types for input `u`
-

### Breakpoint > Minimum

Specify the minimum value that the breakpoint data can have. The default value is [ ] (unspecified).

### Breakpoint > Maximum

Specify the maximum value that the breakpoint data can have. The default value is [ ] (unspecified).

### Index > Data Type

---

**Note:** This parameter displays only when you set **Output selection** on the **Main** tab to **Index and fraction** or **Index only**.

---

Specify a data type that can index all elements in the breakpoint data set. You can:

- Select a built-in integer data type from the list.
- Specify an integer data type using a fixed-point representation.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the index data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

### Fraction > Data Type

---

**Note:** This parameter displays only when you set **Output selection** on the **Main** tab to **Index and fraction** or **Index only**.

---

Specify the data type of the interval fraction. You can:

- Select a built-in data type from the list.
- Specify data type inheritance through an internal rule.
- Specify a fixed-point data type using the [Slope Bias] or binary-point-only scaling representation.

- If you use the [Slope Bias] representation, the scaling must be trivial — that is, the slope is 1 and the bias is 0.
- If you use the binary-point-only representation, the fixed power-of-two exponent must be less than or equal to zero.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the fraction data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink User's Guide for more information.

## Output

---

**Note:** This parameter displays only when you set **Output selection** on the **Main** tab to **Index and fraction** or **Index only**.

---

Output a nonvirtual bus. Use the **Bus: <object name>** template to specify a bus object. Replace <object name> with the name of a bus object that contains the index and fraction signals.

- The bus object must contain two elements. The first element corresponds to the index signal and the second to the fraction signal.
- The index and fraction bus element signals cannot be bus signals.
- The data type and the complexity of the bus elements must meet the same constraints that apply to the index and fraction signals if you set **Output selection** to **Index and fraction**.

To create the bus object with the index and fraction bus elements, use MATLAB code similar to this, customizing the bus object name and the names and data types of the bus elements.

```
% Bus object: kfBus
elems(1) = Simulink.BusElement;
elems(1).Name = 'Index';
elems(1).DataType = 'int8';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Fraction';
```

```
elems(2).DataType = 'double';
```

```
kfBus = Simulink.Bus;  
kfBus.Elements = elems;  
clear elems;
```

Alternatively, you can use the Bus Editor to create or modify the bus object to use with the Prelookup block.

If you feed the bus output signal from this block to an Interpolation Using Prelookup block, select the **Require index and fraction as bus** check box in that block.

---

**Note:** Using the Fixed-Point Tool data type override option overrides bus objects with new bus objects that replace fixed-point data types with floating-point data types.

Overridden bus objects used with the Prelookup block can cause an error because the block does not accept floating-point data types for the first element in the bus.

If you encounter this issue, using the **Fix** button redefines the original bus object to protect it from being overridden. For example, suppose you define the first element of the bus object to be an int32.

```
myBus.Elements(1).DataType  
int32
```

Clicking the **Fix** button redefines the first bus element to be:

```
myBus.Elements(1).DataType = 'fixdt('int32','DataTypeOverride','Off')
```

---

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

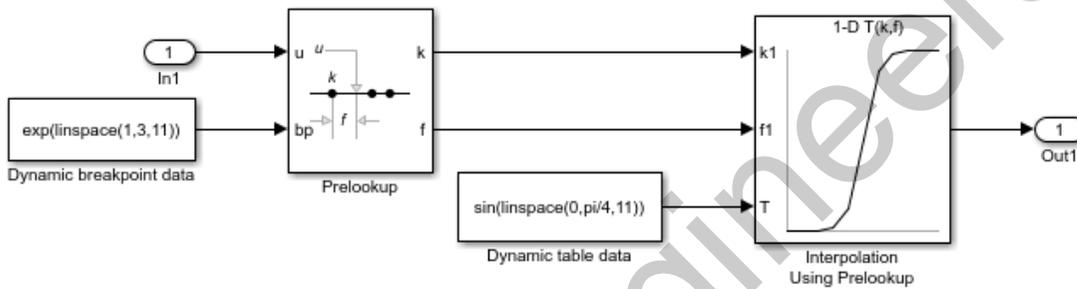

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Simulink Fixed Point™ documentation.

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

## Examples

### Prelookup with External Breakpoint Specification

In the following model, a Constant block feeds the breakpoint dataset to the **bp** input port of the Prelookup block.

The Prelookup block inherits the following breakpoint attributes from the **bp** input port:

Breakpoint Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Similarly, a Constant block feeds the table data values to the **T** input port of the Interpolation Using Prelookup block, which inherits the following table attributes:

Table Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoint and table data as single-precision,

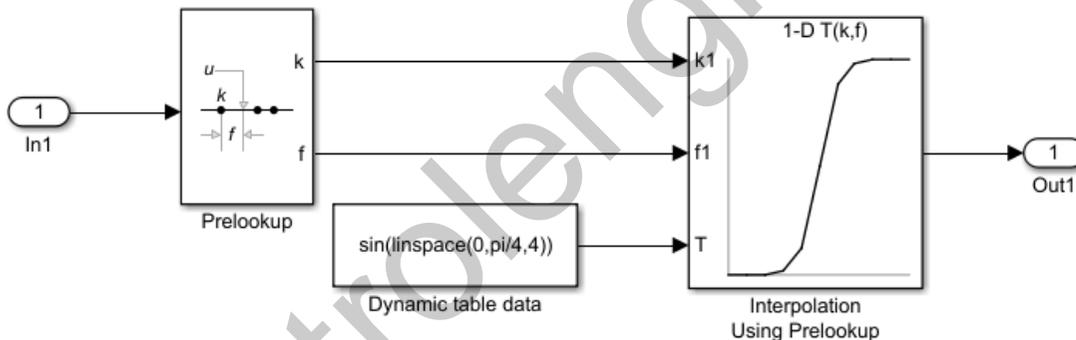

floating-point data. Using a lower-precision data type to store breakpoint and table data reduces the memory requirement.

## Prelookup with Even Spaced Breakpoint Specification

In this model, you specify evenly spaced breakpoint data to the Prelookup block.

The **Breakpoint Specification** parameter is set to **Even Spacing**. The parameters **First point**, **Spacing**, and **Number of points** are set to 25, 12, and 4 respectively. Specifying these parameters creates four evenly spaced breakpoints: [25, 37, 49, 61].

Specifying even spacing is an alternative way to specify breakpoints that are evenly spaced. You can also set **Breakpoint Specification** to **Explicit** values and set **Value** to [25:12:61].

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoints and table data as double.

For other examples, see “Prelookup and Interpolation Blocks” in the Simulink documentation.

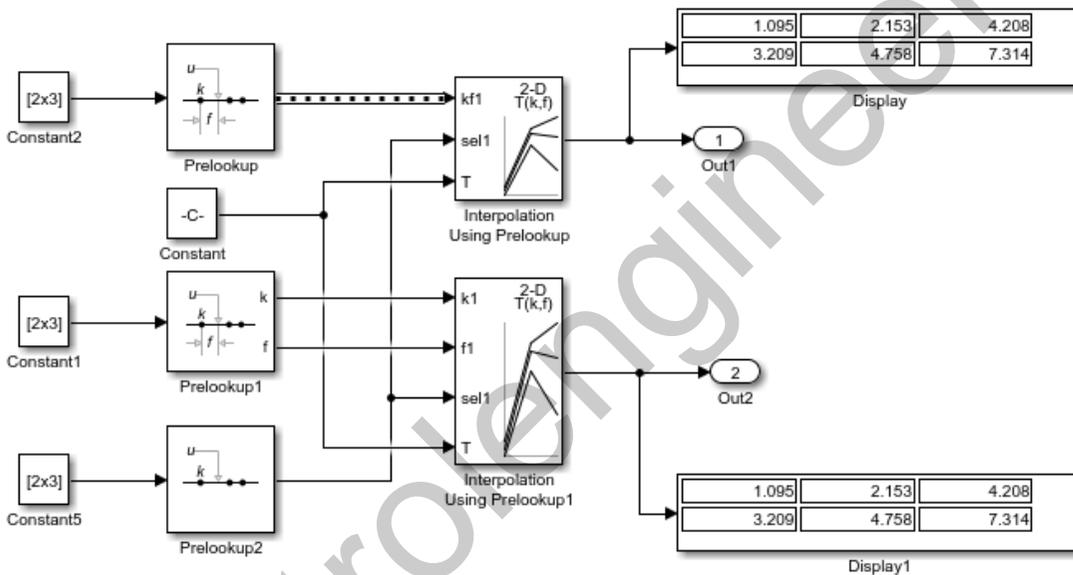

## Use a Bus for Index and Fraction

You can use a bus object to specify the index ( $k$ ) and fraction ( $f$ ) in the Prelookup block and then use that bus as input to an Interpolation Using Prelookup block. This example

shows how to use a bus signal and how to get the same results without using a bus object.

Open the model and simulate it.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_prelookup_bus.slx'))))
sim('ex_prelookup_bus')
```

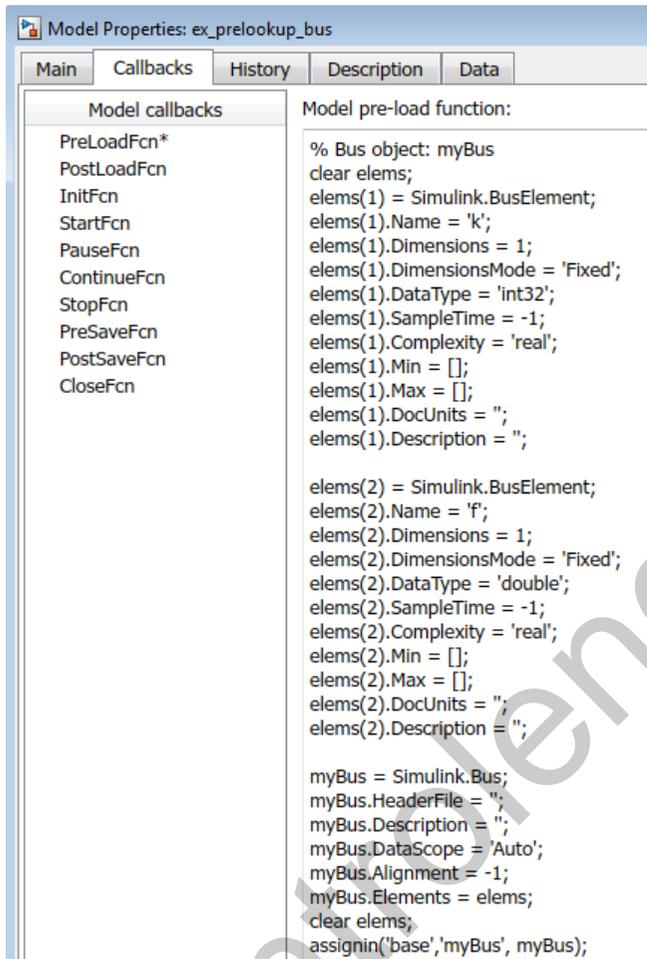

At the top of the model, open the **Prelookup** block parameters dialog box. In the **Main** tab, note that **Output selection** is set to Index and fraction as bus.

In the **Data Types** tab, note that **Output** is set to Bus: myBus.

In the Simulink Editor, select **File > Model Properties** and open the **Callbacks** tab.

The code defines the bus object **myBus**, which specifies the index as the first bus element and the fraction as the second element.

In the Interpolation Using Prelookup block parameters dialog box, in the **Main** tab, note that **Require index and fraction as bus** check box is selected. That option configures the block to use the bus output from the Prelookup block.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
------------	--

Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Interpolation Using Prelookup

Introduced in R2006b

Controlengineers.ir

## Probe

Output signal attributes, including width, dimensionality, sample time, and complex signal flag

## Library

Signal Attributes

## Description

The Probe block outputs selected information about the signal on its input. The block can output the input signal's width, dimensionality, sample time, and a flag indicating whether the input is a complex-valued signal. The block has one input port. The number of output ports depends on the information that you select for probing, that is, signal dimensionality, sample time, and/or complex signal flag. Each probed value is output as a separate signal on a separate output port. The block accepts real or complex-valued signals of any built-in data type. It outputs signals of type `double`. During simulation, the block icon displays the probed data.

## Data Type Support

The Probe block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

- Enumerated (input only)
- Bus object

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

You can use an array of buses as an input signal to a Probe block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Parameters

### Probe width

Select to output the width, or number of elements, of the probed signal.

### Probe sample time

Select to output the sample time of the probed signal. The output is a two-element vector that specifies the period and offset of the sample time, respectively. See “Specify Sample Time” for more information.

### Detect complex signal

Select to output 1 if the probed signal is complex; otherwise, 0.

### Probe signal dimensions

Select to output the dimensions of the probed signal.

---

**Note:** The Probe block ignores the **Data type override** setting of the Fixed-Point Tool.

---

### Data type for width

Select the output data type for the width information.

### Data type for sample time

Select the output data type for the sample time information.

### Data type for signal complexity

Select the output data type for the complexity information.

### Data type for signal dimensions

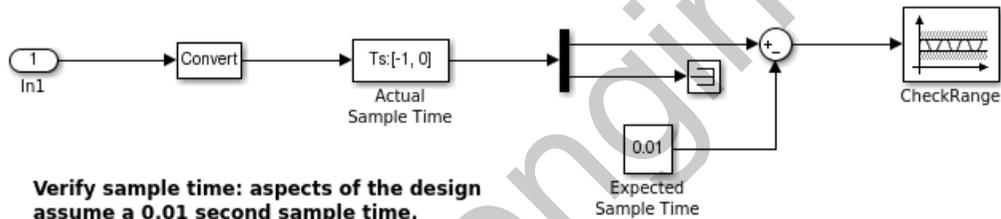

Select the output data type for the dimensions information.

**Note:** For **Data type for width**, **Data type for sample time**, and **Data type for signal dimensions**, the Boolean data type is not supported. Furthermore, if you select Same as input in any of these drop-down lists, and the block's input signal data type is Boolean, when you simulate your model, you see an error.

## Examples

The `sldemo_fuelsys` model shows how you can use the Probe block.

In the `fuel_rate_control/validate_sample_time` subsystem, the Probe block determines the sample time of the input signal to verify that it matches the assumed value of the design:

**Verify sample time: aspects of the design assume a 0.01 second sample time.**

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

# Product

Multiply and divide scalars and nonscalars or multiply and invert matrices

## Library

Math Operations

## Description

The Divide and Product of Elements blocks are variants of the Product block.

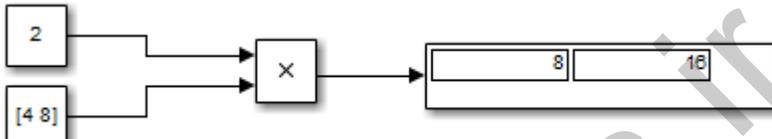

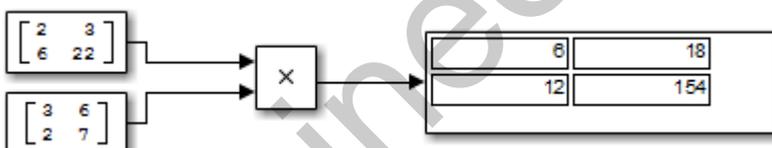

- For information on the Divide block, see [Divide](#).
- For information on the Product of Elements block, see [Product of Elements](#).

The Product block outputs the result of multiplying two inputs: two scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The default parameter values that specify this behavior are:

- **Multiplication:** Element-wise (.\*)
- **Number of inputs:** 2

The following table shows the output of the Product block for example inputs using default block parameter values.

Inputs and Behavior	Example
<p><b>Scalar X Scalar</b></p> <p>Output the product of the two inputs.</p>	

Inputs and Behavior	Example
<p><b>Scalar X Nonscalar</b></p> <p>Output a nonscalar having the same dimensions as the input nonscalar. Each element of the output nonscalar is the product of the input scalar and the corresponding element of the input nonscalar.</p>	
<p><b>Nonscalar X Nonscalar</b></p> <p>Output a nonscalar having the same dimensions as the inputs. Each element of the output is the product of corresponding elements of the inputs.</p>	

The Product block (or the Divide block or Product of Elements block, if appropriately configured) can:

- Numerically multiply and divide any number of scalar, vector, or matrix inputs
- Perform matrix multiplication and division on any number of matrix inputs

The Product block performs scalar or matrix multiplication, depending on the value of the **Multiplication** parameter. The block accepts one or more inputs, depending on the **Number of inputs** parameter. The **Number of inputs** parameter also specifies the operation to perform on each input.

The Product block can input any combination of scalars, vectors, and matrices for which the operation to perform has a mathematically defined result. The block performs the specified operations on the inputs, then outputs the result.

The Product block has two modes: *Element-wise mode*, which processes nonscalar inputs element by element, and *Matrix mode*, which processes nonscalar inputs as matrices. The next two sections describe these two modes.

## Element-wise Mode

When the value of the **Multiplication** parameter is **Element-wise (.\*)**, the Product block is in *Element-wise mode*, in which it operates on the individual numeric elements of any nonscalar inputs. The MATLAB equivalent is the `.*` operator. In element-wise mode, the Product block can perform a variety of multiplication, division, and arithmetic inversion operations.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each is multiplied or divided to form the output. When the Product block in Element-wise mode has only one input, it is functionally equivalent to a **Product of Elements** block. When the block has multiple inputs, any nonscalar inputs must have identical dimensions, and the block outputs a nonscalar with those dimensions. To calculate the output, the block first expands any scalar input to a nonscalar that has the same dimensions as the nonscalar inputs.

This table shows the output of the Product block for example inputs, using the indicated values for the **Number of inputs** parameter.

Parameter Values	Examples
Number of inputs: 2	
Number of inputs: */	
Number of inputs: /**/	

Parameter Values	Examples
Number of inputs: **	
Number of inputs: */*	

## Matrix Mode

When the value of the **Multiplication** parameter is `Matrix(*)`, the Product block is in *Matrix mode*, in which it processes nonscalar inputs as matrices. The MATLAB equivalent is the `*` operator. In Matrix mode, the Product block can invert a single square matrix, or multiply and divide any number of matrices that have dimensions for which the result is mathematically defined.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each input matrix is multiplied or divided to form the output. The syntax of **Number of inputs** is the same as in Element-wise mode. The difference between the modes is in the type of multiplication and division that occur.

## Expected Differences Between Simulation and Code Generation

For element-wise operations on complex floating-point inputs, simulation and code generation results might differ in near-overflow cases. Although **complex numbers** is selected and **non-finite numbers** is not selected on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, the code generator does not emit special case code for intermediate overflows. This method improves the efficiency of embedded operations for the general case that does not include extreme values. If the inputs might include extreme values, please manage these cases explicitly.

The generated code might not produce the exact same pattern of NaN and inf values as simulation when these values are mathematically meaningless. For example, if the

simulation output contains a NaN, output from the generated code also contains a NaN, but not necessarily in the same place.

## Data Type Support

The Product block accepts real or complex signals of any numeric data type that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

The Product block does not support numeric division for complex signals with `boolean` or fixed-point data types. For other types, the block accepts complex signals as divisors only when the input and output signals all specify the same built-in data type. In this case, however, the block ignores its specified rounding mode.

The Product block accepts multidimensional signals when operating in Element-wise mode, but not when operating in Matrix mode. See “Signal Dimensions”, “Element-wise Mode” on page 1-1356, and “Matrix Mode” on page 1-1357 for more information.

## Parameters

### Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

### Settings

**Default:** 2 for Product block, \* / for Divide block, and \* for Product of Elements block

- 1 or \* or /

Has one input. In element-wise mode, processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or \*, the block outputs the input value. If the value is /, the input must be a square matrix

(including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

- **Integer value > 1**

Has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

- **Unquoted string of two or more \* and / characters**

Has the number of inputs given by the length of the character vector. Each input that corresponds to a \* character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 for more information.

### Dependency

Setting **Number of inputs** to \* and selecting **Element-wise(.\*)** for **Multiplication** enables the **Multiply over** parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

### Settings

**Default:** **Element-wise(.\*)**

**Element-wise(.\*)**

Operate in Element-wise mode.

**Matrix(\*)**

Operate in Matrix mode.

## Dependency

Selecting **Element-wise (.\*)** and setting **Number of inputs** to \* enable the following parameter:

- **Multiply over**

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiply over

Affect multiplication on matrix input.

## Settings

**Default:** All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

## Dependencies

- Enable this parameter by selecting **Element-wise (.\*)** for **Multiplication** and setting **Number of inputs** to \* or 1 or /.
- Setting this parameter to **Specified dimension** enables the **Dimension** parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Dimension

Affect multiplication on matrix input.

## Settings

**Default:** 1

**Minimum:** 1

**Maximum:** 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

## Tips

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or \*

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

## Dependency

Enable this parameter by selecting Specified dimension for **Multiply over**.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Require all inputs to have the same data type

Require that all inputs have the same data type.

### Settings

**Default:** Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note: Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

**Command-Line Information**

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

Controlengineers.ir

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

### Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

### Inherit: Inherit via back propagation

Use data type of the driving block.

### Inherit: Same as first input

Use data type of the first input signal.

`double`

Output data type is `double`.

`single`

Output data type is `single`.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Control Signal Data Types”.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

### Mode

Select the category of data to specify.

### Settings

**Default:** `Inherit`

## Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as first input

## Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

## Fixed point

Fixed-point data types.

## Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

## Dependency

Clicking the **Show data type assistant** button enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## See Also

See “Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

## Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

## Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

## Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

## Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > Binary point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

## Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

## Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Rounding” (Fixed-Point Designer).

### Saturate on integer overflow

Specify whether overflows saturate.

#### Settings

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

# Product of Elements

Copy or invert one scalar input, or collapse one nonscalar input

## Library

Math Operations

## Description

The Divide and Product blocks are variants of the Product of Elements block.

- For information on the Divide block, see **Divide**.
- For information on the Product block, see **Product**.

The Product of Elements block inputs one scalar, vector, or matrix. You can use the block to:

- Copy a scalar input unchanged
- Invert a scalar input (divide 1 by it)
- Collapse a vector or matrix to a scalar by multiplying together all elements or taking successive inverses of the elements
- Collapse a matrix to a vector by multiplying together the elements of each row or column or taking successive inverses of the elements of each row or column

The Product of Elements block is functionally a **Product** block that has two preset parameter values:

- **Multiplication:** Element-wise ( .\* )
- **Number of inputs:** \*

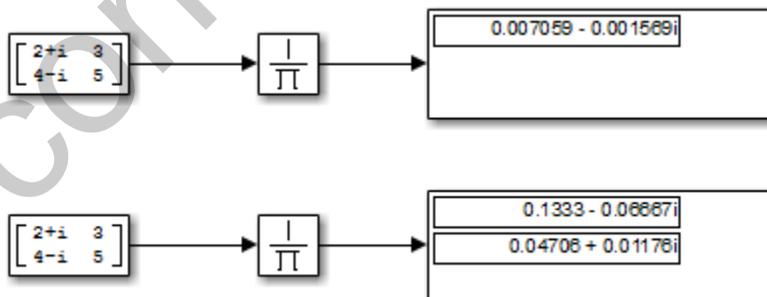

Setting non-default values for either of those parameters can change a Product of Elements block to be functionally equivalent to a Product block or a Divide block. See the documentation of those two blocks for more information.

## Algorithm

The Product of Elements block uses the following algorithms to perform element-wise operations on inputs of floating-point, built-in integer, and fixed-point types:

Input	Element-Wise Operation	Algorithm
Real scalar, $u$	Multiplication	$y = u$
	Division	$y = 1/u$
Real vector or matrix, with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$
Complex scalar, $u$	Multiplication	$y = u$
	Division	$y = 1/u$
Complex vector or matrix, with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$

If the specified dimension for element-wise multiplication or division is a row or column of a matrix, the algorithm applies to that row or column. For example, consider the following model:

The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- $y = (((1/2+i)/3)/4-i)/5)$

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- $y(1) = ((1/2+i)/3)$
- $y(2) = ((1/4-i)/5)$

## Parameters

### Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

### Settings

**Default:** \*

- **1 or \***
  - Copies a scalar input unchanged
  - Collapses a vector input to a scalar by multiplying all elements together
  - Collapses a matrix input to a scalar or vector by multiplying elements together based on the **Multiply over** parameter

For more information, see “Algorithm” on page 1-1377.

- /
  - Outputs the arithmetic inverse of a scalar input
  - Collapses a vector input to a scalar by taking successive inverses of the elements
  - Collapses a matrix input to a scalar or vector by taking successive inverses of elements based on the **Multiply over** parameter

For more information, see “Algorithm” on page 1-1377.

- **Integer value > 1**

Has the number of inputs given by the integer value. The block becomes a product block and the input are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 in the Product documentation for more information.

- **Unquoted string of two or more \* and / characters**

Has the number of inputs given by the length of the character vector. The block becomes a product or divide block and multiplies each input that corresponds to a \* character into the output. Each input that corresponds to a / character is divided into the output. The operations occur in Element-wise mode or Matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1356 and “Matrix Mode” on page 1-1357 in the Product block reference page for more information.

### Dependency

Setting **Number of inputs** to \* and selecting **Element-wise(.\*)** for **Multiplication** enables the following **Multiply over** parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

### Settings

**Default:** Element-wise(.\*)

Element-wise(.\*)

Operate in Element-wise mode.

Matrix(\*)

Operate in Matrix mode.

## Dependency

Selecting **Element-wise (.\*)** and setting **Number of inputs** to \* enable the following parameter:

- **Multiply over**

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Multiply over

Affect multiplication on matrix input.

## Settings

**Default:** All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

## Dependencies

- Enable this parameter by selecting **Element-wise (.\*)** for **Multiplication** and setting **Number of inputs** to \* or 1 or /.
- Setting this parameter to **Specified dimension** enables the **Dimension** parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Dimension

Affect multiplication on matrix input.

## Settings

**Default:** 1

**Minimum:** 1

**Maximum:** 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

## Tips

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or \*

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

## Dependency

Enable this parameter by selecting Specified dimension for **Multiply over**.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Require all inputs to have the same data type

Require that all inputs have the same data type.

### Settings

**Default:** Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note: Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

**Command-Line Information**

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

Controlengineers.ir

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

### Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

### Inherit: Inherit via back propagation

Use data type of the driving block.

### Inherit: Same as first input

Use data type of the first input signal.

`double`

Output data type is `double`.

`single`

Output data type is `single`.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.  
`int32`

Output data type is `int32`.  
`uint32`

Output data type is `uint32`.  
`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.  
`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.  
`<data type expression>`

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Control Signal Data Types”.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

### Mode

Select the category of data to specify.

### Settings

**Default:** `Inherit`

## Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as first input

## Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

## Fixed point

Fixed-point data types.

## Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

## Dependency

Clicking the **Show data type assistant** button enables this parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## See Also

See “Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

## Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

## Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

## Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

## See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

## Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > Binary point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

## Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

## Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Rounding” (Fixed-Point Designer).

### Saturate on integer overflow

Specify whether overflows saturate.

#### Settings

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

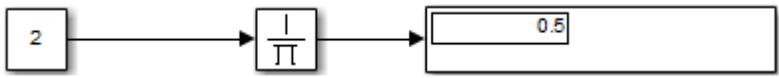

**Type:** character vector

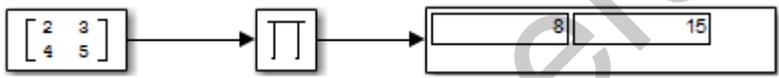

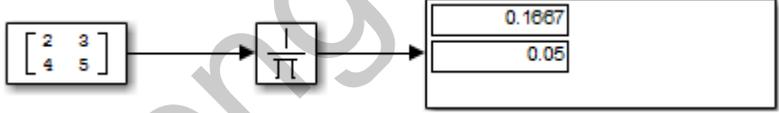

**Value:** 'off' | 'on'

**Default:** 'off'

### Examples

This table shows the output of the Product of Elements block for example inputs using default block parameter values, except as shown in the table.

Parameter Values	Examples
<b>Multiplication:</b> Element-wise (.*)  <b>Number of inputs:</b> *	
<b>Multiplication:</b> Element-wise (.*)  <b>Number of inputs:</b> /	
<b>Multiplication:</b> Element-wise (.*)  <b>Number of inputs:</b> *	

Parameter Values	Examples

# Pulse Generator

Generate square wave pulses at regular intervals

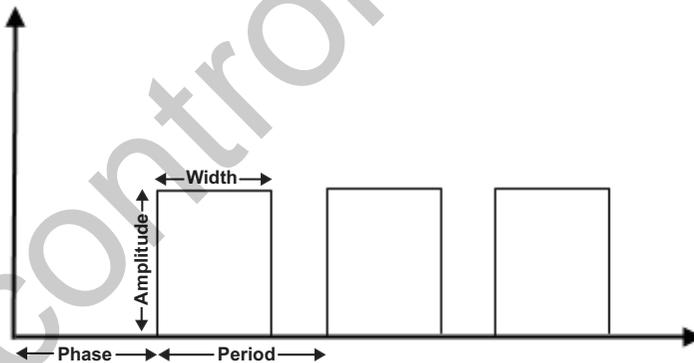

## Library

Sources

## Description

The Pulse Generator block generates square wave pulses at regular intervals. The block waveform parameters, **Amplitude**, **Pulse Width**, **Period**, and **Phase delay**, determine the shape of the output waveform. The following diagram shows how each parameter affects the waveform.

The Pulse Generator can emit scalar, vector, or matrix signals of any real data type. To cause the block to emit a scalar signal, use scalars to specify the waveform parameters.

To cause the block to emit a vector or matrix signal, use vectors or matrices, respectively, to specify the waveform parameters. Each element of the waveform parameters affects the corresponding element of the output signal. For example, the first element of a vector amplitude parameter determines the amplitude of the first element of a vector output pulse. All the waveform parameters must have the same dimensions after scalar expansion. The data type of the output is the same as the data type of the **Amplitude** parameter.

This block output can be generated in time-based or sample-based modes, determined by the **Pulse type** parameter.

## Time-Based Mode

In time-based mode, Simulink computes the block output only at times when the output actually changes. This approach results in fewer computations for the block output over the simulation time period. Activate this mode by setting the **Pulse type** parameter to **Time based**.

The block does not support a time-based configuration that results in a constant output signal. Simulink returns an error if the parameters **Pulse Width** and **Period** satisfy either of these conditions:

$$Period * \frac{PulseWidth}{100} = 0$$

$$Period * \frac{PulseWidth}{100} = Period$$

Depending on the pulse waveform characteristics, the intervals between changes in the block output can vary. For this reason, a time-based Pulse Generator block has a variable sample time. The sample time color of such blocks is brown (see “View Sample Time Information” for more information).

Simulink cannot use a fixed-step solver to compute the output of a time-based pulse generator. If you specify a fixed-step solver for models that contain time-based pulse generators, Simulink computes a fixed sample time for the time-based pulse generators. Then the time-based pulse generators simulate as sample based.

If you use a fixed-step solver and the **Pulse type** is **Time based**, choose the step size such that the period, phase delay, and pulse width (in seconds) are integer multiples of

the solver step size. For example, suppose that the period is 4 seconds, the pulse width is 75% (that is, 3 s), and the phase delay is 1 s. In this case, the computed sample time is 1 s. Therefore, choose a fixed-step size of 1 or a number that divides 1 exactly (e.g., 0.25). You can guarantee this by setting the fixed-step solver step size to **auto** on the **Solver** pane of the Configuration Parameters dialog box.

## Sample-Based Mode

In sample-based mode, the block computes its outputs at fixed intervals that you specify. Activate this mode by setting the **Pulse type** parameter to **Sample based**.

An important difference between the time-based and sample-based modes is that in time-based mode, the block output is based on simulation time, and in sample-based mode, the block output depends only on the simulation start, regardless of elapsed simulation time. For more information, see the example “Difference Between Time-Based and Sample-Based Pulse Generation Modes” on page 1-1400.

This block supports reset semantics in sample-based mode. For example, if a Pulse Generator is in a resettable subsystem that hits a reset trigger, the block output resets to its initial condition.

## Data Type Support

The Pulse Generator block outputs real signals of any numeric data type that Simulink supports, including fixed-point data types. The data type of the output signal is the same as that of the **Amplitude** parameter.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Pulse type

The pulse type for this block: **Time based** or **Sample based**. The default is **Time based**.

### Time (t)

Specifies whether to use simulation time or an external signal as the source of values for the output pulse's time variable. If you specify an external source, the block displays an input port for connecting the source. The output pulse differs as follows:

- **Use simulation time:** The block generates an output pulse where the time variable equals the simulation time.
- **Use external signal:** The block generates an output pulse where the time variable equals the value from the input port, which can differ from the simulation time.

### Amplitude

The pulse amplitude. The default is 1.

### Period

The pulse period specified in seconds if the pulse type is time-based or as number of sample times if the pulse type is sample-based. The default is 10 seconds.

### Pulse Width

The duty cycle specified as the percentage of the pulse period that the signal is on if time-based or as number of sample times if sample-based. The default is 5 percent.

### Phase delay

The delay before the pulse is generated specified in seconds if the pulse type is time-based or as number of sample times if the pulse type is sample-based. The default is 0 seconds.

### Sample time

The length of the sample time for this block in seconds. This parameter appears only if the block's pulse type is sample-based. See “Specify Sample Time” in the Simulink User's Guide for more information.

### Interpret vector parameters as 1-D

If you select this check box and the other parameters are one-row or one-column matrices, after scalar expansion, the block outputs a 1-D signal (vector). Otherwise the output dimensionality is the same as that of the other parameters. See “Determining the Output Dimensions of Source Blocks” in the “Working with Signals” chapter of the Simulink User's Guide.

## Examples

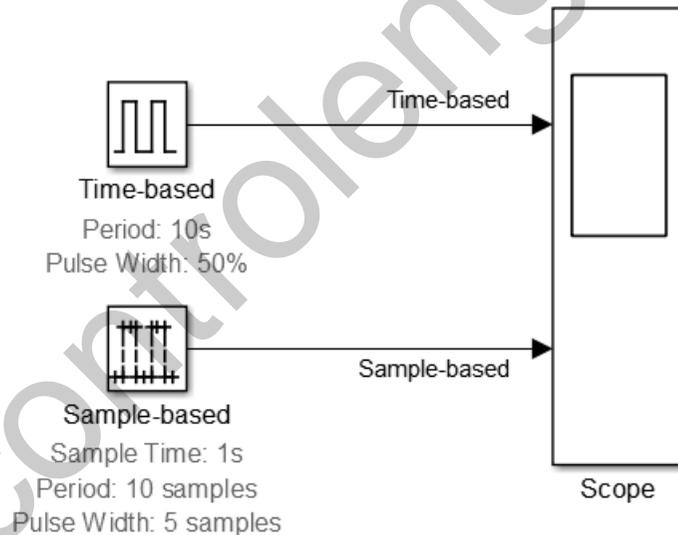

The following Simulink examples show how to use the Pulse Generator block:

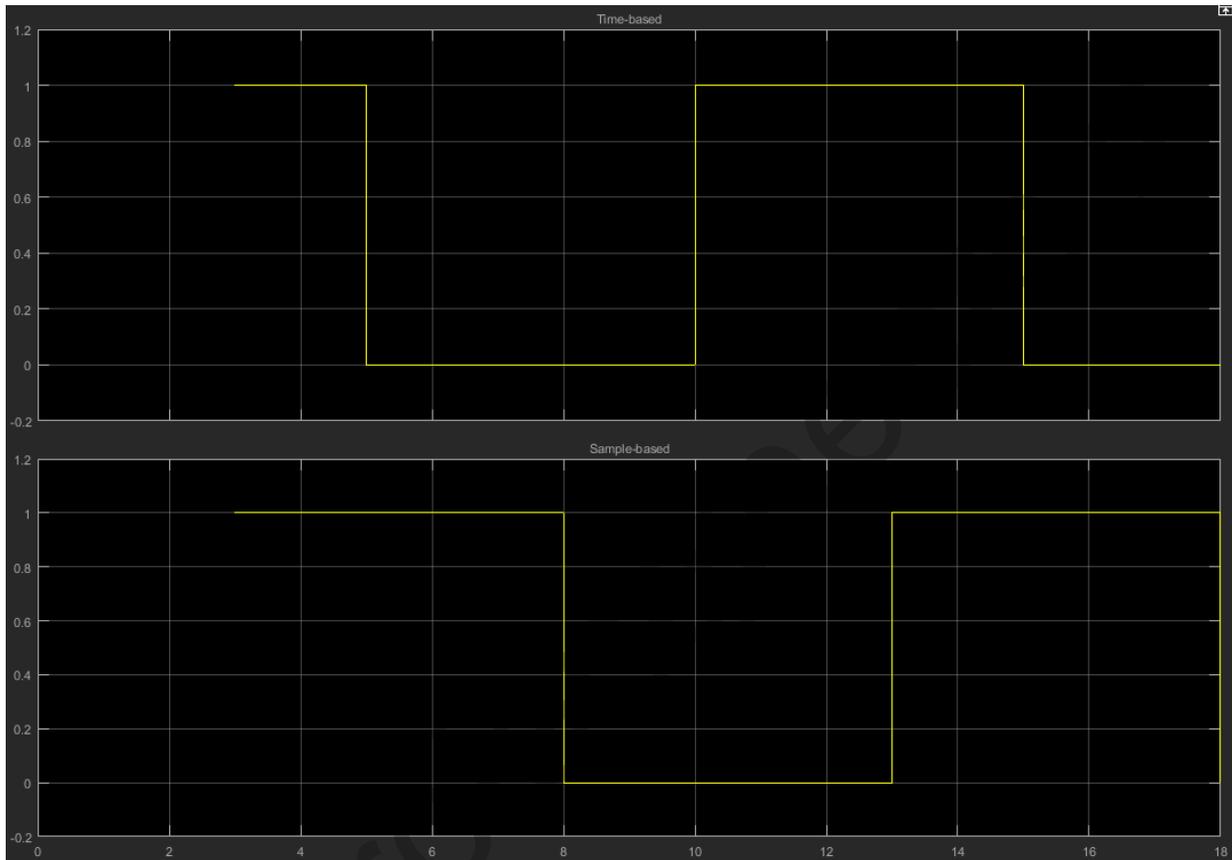

- sldemo\_auto\_climatecontrol
- sldemo\_boiler

## Difference Between Time-Based and Sample-Based Pulse Generation Modes

This example shows the difference in the behavior of the Pulse Generator block in time-based and sample-based modes.

Consider a model with two Pulse Generator blocks. In one block, the **Pulse type** parameter is set to **Time based**. In the other block, it is set to **Sample based**. Both blocks are set up to output a Boolean pulse of 10 seconds: 5 seconds **on** followed by 5 seconds **off**. The simulation runs for 15 seconds from a start time of 3 seconds to a stop time of 18 seconds, specified in the Model Configuration Parameters dialog box. The figure shows the block diagram for this model and the simulation output in the Scope block.

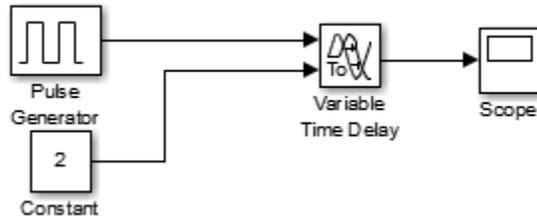

You can see that simulation output starts at 3 seconds, as expected. Notice that the time-based Pulse Generator produces a logical **on** for only 2 seconds, after which its output changes to **off** at  $t = 5$  seconds. This is because this block starts computing its output from  $t = 0$  seconds, even though it doesn't output it until the simulation starts at  $t = 3$  seconds. The time-based block depends on simulation time for its output.

The sample-based block outputs a pulse of 5 seconds **on** followed by 5 seconds **off**. In this case, the block's output does not depend on simulation time, and starts only when the simulation starts.

## Tune Phase Delay Parameter During Simulation

You cannot tune the value of the **Phase delay** parameter during simulation. As a workaround, you can add a Constant block and a Variable Time Delay block.

In the Pulse Generator block, set the value of the **Phase delay** parameter to 0. Use the Constant block to specify the delay time (in seconds).

To tune the delay time during simulation, change the value stored in the Constant block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Push Button

Set value of tunable parameter or variable by holding button

## Library

Dashboard

## Description

The Push Button block enables you to control tunable parameters and variables in your model during simulation. The block sets a value of a tunable parameter or variable by selecting and holding the button. When the push button is not selected, the value is set back to the default value.

To control a tunable parameter or variable using the Push Button block, double-click the Push Button block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

## Limitations

The Push Button block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make

Limitation	Workaround
	the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as engine_1.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### Button Text

The push button text label.

### Settings

**Default:** Button

Specify this label as a character vector.

### On Value

The value when the button is pushed and held.

## Settings

**Default:** 1

Specify this number as a finite, real, double, scalar value.

## Label

Position of the block label or instructional text if the block is not connected.

## Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Quantizer

Discretize input at specified interval

## Library

Discontinuities

## Description

The Quantizer block passes its input signal through a stair-step function so that many neighboring points on the input axis are mapped to one point on the output axis. The effect is to quantize a smooth signal into a stair-step output. The output is computed using the round-to-nearest method, which produces an output that is symmetric about zero.

$$y = q * \text{round}(u/q)$$

where  $y$  is the output,  $u$  the input, and  $q$  the **Quantization interval** parameter.

## Data Type Support

The Quantizer block accepts and outputs real or complex signals of type `single` or `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Quantization interval

The interval around which the output is quantized. Permissible output values for the Quantizer block are  $n*q$ , where  $n$  is an integer and  $q$  the **Quantization interval**. The default is 0.5.

### Treat as gain when linearizing

Simulink software by default treats the Quantizer block as unity gain when linearizing. This setting corresponds to the large-signal linearization case. If you clear this check box, the linearization routines assume the small-signal case and set the gain to zero.

### Sample time

---

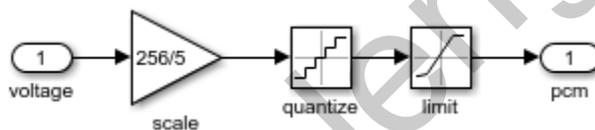

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

The `sldemo_boiler` model shows how you can use the Quantizer block.

The Quantizer block appears in the Boiler Plant model/digital thermometer/ADC subsystem.

The ADC subsystem digitizes the input analog voltage by:

- Multiplying the analog voltage by 256/5 with the Gain block
- Rounding the value to integer floor with the Quantizer block
- Limiting the output to a maximum of 255 (the largest unsigned 8-bit integer value) with the Saturation block

For more information, see “Explore the Fixed-Point “Bang-Bang Control” Model” (Stateflow) in the Stateflow documentation.

## Characteristics

Data Types	Double   Single
------------	-----------------

Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Quarter Gauge

Display input value on ninety degree scale

### Library

Dashboard

### Description

The Quarter Gauge block displays connected signals during simulation on a circular ninety degree gauge.

To view data from a signal on the Quarter Gauge block, double-click the Quarter Gauge block to open the dialog box. Select a signal in the model canvas. The signal appears in the dialog box **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal to the block.

You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

You can also add scale colors that appear on the outside of the Quarter Gauge block scale using the **Scale Colors** table.

### Limitations

The Quarter Gauge block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

If you turn off streaming for a signal connected to any dashboard gauge, the connection shows as broken, and signal data does not stream to the block. To view signal data again, double-click the gauge and reconnect the signal.

External mode simulation does not support the Quarter Gauge block.

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a signal to connect and display.

To view the data from a signal, select a signal in the model. The signal appears in the **Connection** table. Select the option button next to the signal you want to display. Click **Apply** to connect the signal.

### Settings

The table has a row for the signal connected to the block. If there are no signals selected in the model or the block is not connected to any signals, then the table is empty.

### Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

### Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

### Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

### Scale Colors

Specify ranges of color bands on the outside of the scale. Specify the minimum and maximum color range to display on the gauge.

### Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

### Top

Show the label at the top of the block.

### Bottom

Show the label at the bottom of the block.

### Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

Controlengineers.ir

## Ramp

Generate constantly increasing or decreasing signal

## Library

Sources

## Description

The Ramp block generates a signal that starts at a specified time and value and changes by a specified rate. The block's **Slope**, **Start time**, and **Initial output** parameters determine the characteristics of the output signal. All must have the same dimensions after scalar expansion.

## Data Type Support

The Ramp block outputs signals of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Slope

Specify the rate of change of the generated signal. The default is 1.

### Start time

Specify the time at which the block begins generating the signal. The default is 0.

### Initial output

Specify the initial value of the output signal. The default is 0.

**Interpret vector parameters as 1-D**

If you select this option and the other parameters are one-row or one-column matrices, after scalar expansion, the block outputs a 1-D signal (vector). Otherwise, the output dimensionality is the same as that of the other parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

**Examples**

The following Simulink examples show how to use the Ramp block:

- `sldemo_VariableTransportDelay_pipe`

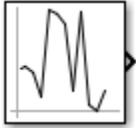

**Characteristics**

Data Types	Double
Sample Time	Inherited from downstream block
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

**Introduced before R2006a**

## Random Number

Generate normally distributed random numbers

### Library

Sources

### Description

The Random Number block generates normally distributed random numbers. To generate uniformly distributed random numbers, use the Uniform Random Number block.

You can generate a repeatable sequence using any Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts. By default, the block produces a sequence that has a mean of 0 and a variance of 1. To generate a vector of random numbers with the same mean and variance, specify the **Seed** parameter as a vector.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

## Data Type Support

The Random Number block outputs a real signal of type **double**. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Mean

Specify the mean of the random numbers. The default is 0.

### Variance

Specify the variance of the random numbers. The default is 1.

### Seed

Specify the starting seed for the random number generator. The default is 0.

The seed must be 0 or a positive integer. Output is repeatable for a given seed.

### Sample time

Specify the time interval between samples. The default is 0.1, which matches the default sample time of the **Band-Limited White Noise** block. See “Specify Sample Time” in the Simulink documentation for more information.

### Interpret vector parameters as 1-D

If you select this check box and the other parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. Otherwise, the block outputs a signal of the same dimensionality as the other parameters. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

## Characteristics

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Code Generation	Yes
-----------------	-----

The generator algorithm is identical to the one used in MATLAB Version 4.0 by the `rand` and `randn` functions. For details on the `mcg16807` algorithm, see “Choosing a Random Number Generator” (MATLAB) in the MATLAB documentation.

To use other algorithms supported by MATLAB in a Simulink model, generate a stream of random numbers in MATLAB, and store the output as a `.mat` file. Use this `.mat` file as the random number input for your simulation. For more information, see “Creating and Controlling a Random Number Stream” (MATLAB). To create multiple independent streams using MATLAB, see “Multiple Streams” (MATLAB).

---

**Note:** Using multiple seeds to generate multiple parallel independent streams for a generator algorithm is not recommended for the `mcg16807` algorithm. Instead, use the method described above.

---

Uniform Random Number

Introduced before R2006a

## Rate Limiter

Limit rate of change of signal

## Library

Discontinuities

## Description

The Rate Limiter block limits the first derivative of the signal passing through it. The output changes no faster than the specified limit. The derivative is calculated using this equation:

$$rate = \frac{u(i) - y(i-1)}{t(i) - t(i-1)}$$

$u(i)$  and  $t(i)$  are the current block input and time, and  $y(i-1)$  and  $t(i-1)$  are the output and time at the previous step. The output is determined by comparing  $rate$  to the **Rising slew rate** and **Falling slew rate** parameters:

- If  $rate$  is greater than the **Rising slew rate** parameter ( $R$ ), the output is calculated as

$$y(i) = \Delta t \cdot R + y(i-1).$$

- If  $rate$  is less than the **Falling slew rate** parameter ( $F$ ), the output is calculated as

$$y(i) = \Delta t \cdot F + y(i-1).$$

- If  $rate$  is between the bounds of  $R$  and  $F$ , the change in output is equal to the change in input:

$$y(i) = u(i)$$

When the block is running in continuous mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is zero), the **Initial condition** is ignored. The block output at  $t = 0$  is equal to the initial input:

$$y(0) = u(0)$$

When the block is running in discrete mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is nonzero), the **Initial condition** is preserved:

$$y(-1) = I_c$$

where  $I_c$  is the initial condition. The block output at  $t = 0$  is calculated as if *rate* is outside the bounds of  $R$  and  $F$ . For  $t = 0$ , *rate* is calculated as follows:

$$rate = \frac{u(0) - y(-1)}{sampletime}$$

---

**Note:** You cannot use a Rate Limiter block inside a Triggered Subsystem. Use the Rate Limiter Dynamic block instead.

---

## Data Type Support

The Rate Limiter block accepts and outputs signals of any numeric data type that Simulink supports, except **Boolean**. The Rate Limiter block supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Rising slew rate

Specify the limit of the derivative of an increasing input signal. This parameter is tunable for fixed-point inputs.

### Falling slew rate

Specify the limit of the derivative of a decreasing input signal. This parameter is tunable for fixed-point inputs.

### Sample time mode

Specify the sample time mode, `continuous` or `inherited` from the driving block.

### Initial condition

Set the initial output of the simulation. Simulink software does not allow you to set the initial condition of this block to `inf` or `NaN`.

### Treat as gain when linearizing

Linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the linearization commands to treat the gain as 1; otherwise, the commands treat the gain as 0.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Continuous or inherited (specified in the <b>Sample time mode</b> parameter)
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Rate Limiter Dynamic

Introduced before R2006a

## Rate Limiter Dynamic

Limit rising and falling rates of signal

## Library

Discontinuities

## Description

The Rate Limiter Dynamic block limits the rising and falling rates of the signal.

- The external signal `up` sets the upper limit on the rising rate of the signal.
- The external signal `lo` sets the lower limit on the falling rate of the signal.

Follow these guidelines when using the Rate Limiter Dynamic block:

- Ensure that the data types of `up` and `lo` are the same as the data type of the input signal `u`.

When the lower limit uses a signed type and the input signal uses an unsigned type, the output signal keeps increasing regardless of the input and the limits.

- Use a fixed-step solver to simulate models that contain this block.

Because the Rate Limiter Dynamic block does not support continuous sample time, simulation with a variable-step solver causes an error.

## Data Type Support

The Rate Limiter Dynamic block accepts input signals of the following data types:

- Floating point
- Built-in integer

- Fixed point

The data type of the output signal  $Y$  matches the data type of the input signal  $u$ .

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No

# Rate Transition

Handle transfer of data between blocks operating at different rates

## Library

Signal Attributes

## Description

### Transition Handling Options

The Rate Transition block transfers data from the output of a block operating at one rate to the input of a block operating at a different rate. Use the block parameters to trade data integrity and deterministic transfer for faster response or lower memory requirements. To learn about data integrity and deterministic data transfer, see “Data Transfer Problems” (Simulink Coder) in the Simulink Coder documentation.

Transition Handling Options	Block Parameter Settings
<ul style="list-style-type: none"> <li>• Data integrity</li> <li>• Deterministic data transfer</li> <li>• Maximum latency</li> </ul>	Select: <ul style="list-style-type: none"> <li>• <b>Ensure data integrity during data transfer</b></li> <li>• <b>Ensure deterministic data transfer</b></li> </ul>
<ul style="list-style-type: none"> <li>• Data integrity</li> <li>• Nondeterministic data transfer</li> <li>• Minimum latency</li> <li>• Higher memory requirements</li> </ul>	Select: <ul style="list-style-type: none"> <li>• <b>Ensure data integrity during data transfer</b></li> </ul> Clear: <ul style="list-style-type: none"> <li>• <b>Ensure deterministic data transfer</b></li> </ul>

Transition Handling Options	Block Parameter Settings
<ul style="list-style-type: none"> <li>• Potential loss of data integrity</li> <li>• Nondeterministic data transfer</li> <li>• Minimum latency</li> <li>• Lower memory requirements</li> </ul>	Clear: <ul style="list-style-type: none"> <li>• <b>Ensure data integrity during data transfer</b></li> <li>• <b>Ensure deterministic data transfer</b></li> </ul>

## Dependencies

The behavior of the Rate Transition block depends on:

- Sample times of the ports to which the block connects (see “Effects of Synchronous Sample Times” on page 1-1425 and “Effects of Asynchronous Sample Times” on page 1-1427)
- Priorities of the tasks for the source and destination sample times (see “Sample time properties” in the Simulink documentation)
- Whether the model specifies a fixed- or variable-step solver (see “Solvers” in the Simulink documentation)

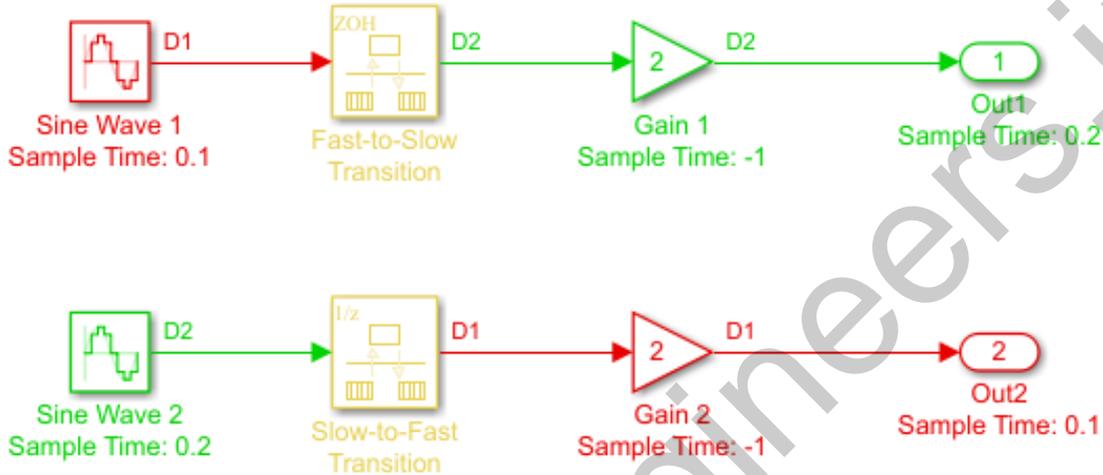

## Block Labels

When you update your diagram, a label appears on the Rate Transition block to indicate simulation behavior.

Label	Block Behavior
ZOH	Acts as a zero-order hold
1/z	Acts as a unit delay
Buf	Copies input to output under semaphore control
Db_buf	Copies input to output using double buffers
Copy	Unprotected copy of input to output
NoOp	Does nothing
Mixed	Expands to multiple blocks with different behaviors

The block behavior label shows the method that ensures safe transfer of data between tasks operating at different rates. You can use the sample-time colors feature (see “View

Sample Time Information” in the Simulink documentation) to display the relative rates that the block bridges. Consider, for example, the following model:

Sample-time colors and the block behavior label show that the Rate Transition block at the top of the diagram acts as a zero-order hold in a fast-to-slow transition and the bottom Rate Transition block acts as a unit delay in a slow-to-fast transition.

For more information, see “Handle Rate Transitions” (Simulink Coder) in the Simulink Coder documentation.

## Effects of Synchronous Sample Times

The following table summarizes how each label appears if the sample times of the input and output ports ( $inTs$  and  $outTs$ ) are periodic, or synchronous.

Block Settings		Block Label		
Rate Transition	Conditions for Rate Transition Block	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
$inTs = outTs$ (Equal)	$inTsOffset < outTsOffset$	None (error)	Buf	Copy or NoOp
	$inTsOffset = outTsOffset$	Copy or NoOp (see note that follows the table)	Copy or NoOp (see	(see note that follows the table)

Block Settings		Block Label		
Rate Transition	Conditions for Rate Transition Block	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
			note that follows the table)	
	$inTsOffset > outTsOffset$	None (error)	Db_buf	
$inTs < outTs$ (Fast to slow)	$inTs = outTs / N$ $inTsOffset, outTsOffset = 0$	ZOH	Buf	
	$inTs = outTs / N$ $inTsOffset \leq outTsOffset$	None (error)		
	$inTs = outTs / N$ $inTsOffset > outTsOffset$	None (error)	Db_buf	
	$inTs \neq outTs / N$	None (error)		
	$inTs = outTs * N$ $inTsOffset, outTsOffset = 0$	1/z	Db_buf	
	$inTs = outTs * N$ $inTsOffset \leq outTsOffset$	None (error)		
$inTs > outTs$ (Slow to fast)	$inTs = outTs * N$ $inTsOffset > outTsOffset$	None (error)		
	$inTs \neq outTs * N$	None (error)		

**KEY**

- $inTs, outTs$ : Sample times of input and output ports, respectively
- $inTsOffset, outTsOffset$ : Sample time offsets of input and output ports, respectively
- $N$ : Integer value  $> 1$

When you select the **Block reduction** parameter on the **All Parameters** tab of the Configuration Parameters dialog box, Copy reduces to NoOp. No code generation occurs

for a Rate Transition block with a NoOp label. To prevent a block from being reduced when block reduction is on, add a test point to the block output (see “Test Points” in the Simulink documentation).

## Effects of Asynchronous Sample Times

The following table summarizes how each label appears if the sample time of the input or output port ( $inTs$  or  $outTs$ ) is not periodic, or asynchronous.

Block Settings	Block Label		
	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
$inTs = outTs$	Copy	Copy	Copy
$inTs \neq outTs$	None (error)	Db_buf	
<b>KEY</b>			
<ul style="list-style-type: none"> <li><math>inTs</math>, <math>outTs</math>: Sample times of input and output ports, respectively</li> </ul>			

## Data Type Support

The Rate Transition block accepts most signals that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

However, do not use the Rate Transition block with frame-based signals. For rate transitions with such signals, use one of these blocks from the DSP System Toolbox instead:

- Buffer
- Unbuffer
- CIC Decimation
- CIC Interpolation
- FIR Decimation
- FIR Interpolation
- Downsample

- Upsample

## Parameters

### Ensure data integrity during data transfer

Selecting this check box results in generated code that ensures data integrity when the block transfers data. If you select this check box and the transfer is nondeterministic (see **Ensure deterministic data transfer** below), depending on the priority of input rate and output rate, the generated code uses a proper algorithm using single or multiple buffers to protect data integrity during data transfer.

Otherwise, the Rate Transition block is either reduced or generates code using a copy operation to effect the data transfer. This unprotected mode consumes less memory. But the copy operation is also interruptible, which can lead to loss of data integrity during data transfers. Select this check box if you want the generated code to operate with maximum responsiveness (i.e., nondeterministically) and data integrity. For more information, see “Rate Transition Block Options” (Simulink Coder) in the Simulink Coder documentation.

### Ensure deterministic data transfer (maximum delay)

Selecting this check box results in generated code that transfers data at the sample rate of the slower block, that is, deterministically. If you do not select this check box, data transfers occur as soon as new data is available from the source block and the receiving block is ready to receive the data. You avoid transfer delays, thus ensuring that the system operates with maximum responsiveness. However, transfers can occur unpredictably, which is undesirable in some applications. For more information, see “Rate Transition Block Options” (Simulink Coder) in the Simulink Coder documentation.

### Initial conditions

This parameter applies only to slow-to-fast transitions. It specifies the initial output of the Rate Transition block at the beginning of a transition when there is no output from the slow block connected to the input of the Rate Transition block. Simulink does not allow the initial output of this block to be `Inf` or `NaN`.

### Output port sample time options

Specifies a mode for setting the output port sample time. The options are:

- **Specify** — Allows you to use the **Output port sample time** parameter to specify the output rate to which the Rate Transition block converts its input rate.

- **Inherit** — Specifies that the Rate Transition block inherits an output rate from the block to which the output port is connected.
- **Multiple of input port sample time** — Allows you to use the **Sample time multiple (>0)** parameter to specify the Rate Transition block output rate as a multiple of its input rate.

If you specify **Inherit** and all blocks connected to the output port also inherit sample time, the fastest sample time in the model applies.

### Output port sample time

This parameter is visible when you set **Output port sample time options to Specify**. Enter a value that specifies the output rate to which the block converts its input rate. The default value (- 1) specifies that the Rate Transition block inherits the output rate from the block to which the output port is connected. See “Specify Sample Time” in the Simulink documentation for information on how to specify the output rate.

### Sample time multiple (>0)

This parameter is visible when you set **Output port sample time options to Multiple of input port sample time**. Enter a positive value that specifies the output rate as a multiple of the input port sample time. The default value (1) specifies that the output rate is the same as the input rate. A value of 0.5 specifies that the output rate is half of the input rate, while a value of 2 specifies that the output rate is twice the input rate.

## Bus Support

The Rate Transition block is a bus-capable block. The input can be a virtual or nonvirtual bus signal, with the restriction that **Initial conditions** must be zero, a nonzero scalar, or a finite numeric structure. For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Rate Transition block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” in the Simulink documentation for more information.

You can use an array of buses as an input signal to a Rate Transition block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	This block supports discrete-to-discrete transitions
Direct Feedthrough	No, for slow-to-fast transitions for which you select the <b>Ensure data integrity during data transfer</b> check box. Yes, otherwise.
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers

# Real-Imag to Complex

Convert real and/or imaginary inputs to complex signal

## Library

Math Operations

## Description

The Real-Imag to Complex block converts real and/or imaginary inputs to a complex-valued output signal.

The inputs can both be arrays (vectors or matrices) of equal dimensions, or one input can be an array and the other a scalar. If the block has an array input, the output is a complex array of the same dimensions. The elements of the real input map to the real parts of the corresponding complex output elements. The imaginary input similarly maps to the imaginary parts of the complex output signals. If one input is a scalar, it maps to the corresponding component (real or imaginary) of all the complex output signals.

## Data Type Support

The block accepts input signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

Complex fixed-point signals must have trivial slope and zero bias. For more information about support for fixed-point data types, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

## Parameters

### Input

Specify the kind of input: a real input, an imaginary input, or both.

### Real (Imag) part

This parameter appears only when you set **Input** to **Real** or **Imag**. If the input is a real-part signal, this parameter specifies the constant imaginary part of the output signal. If the input is the imaginary part, this parameter specifies the constant real part of the output signal. The title of this parameter changes to reflect its usage.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Complex to Real-Imag

Introduced before R2006a

# Relational Operator

Perform specified relational operation on inputs

## Library

Logic and Bit Operations

## Description

### Two-Input Mode

By default, the Relational Operator block compares two inputs using the **Relational operator** parameter that you specify. The first input corresponds to the top input port and the second input to the bottom input port. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.)

You can specify one of the following operations in two-input mode:

Operation	Description
==	TRUE if the first input is equal to the second input
~=	TRUE if the first input is not equal to the second input
<	TRUE if the first input is less than the second input
<=	TRUE if the first input is less than or equal to the second input
>=	TRUE if the first input is greater than or equal to the second input
>	TRUE if the first input is greater than the second input

You can specify inputs as scalars, arrays, or a combination of a scalar and an array.

For...	The output is...
Scalar inputs	A scalar

For...	The output is...
Array inputs	An array of the same dimensions, where each element is the result of an element-by-element comparison of the input arrays
Mixed scalar and array inputs	An array, where each element is the result of a comparison between the scalar and the corresponding array element

The input with the smaller positive range is converted to the data type of the other input offline using round-to-nearest and saturation. This conversion occurs before the comparison.

You can specify the output data type using the **Output data type** parameter. The output equals 1 for TRUE and 0 for FALSE.

---

**Tip:** Select an output data type that represents zero exactly. Data types that satisfy this condition include signed and unsigned integers and any floating-point data type.

---

## One-Input Mode

When you select one of the following operations for **Relational operator**, the block switches to one-input mode.

Operation	Description
isInf	TRUE if the input is Inf
isNaN	TRUE if the input is NaN
isFinite	TRUE if the input is finite

For an input that is not floating point, the block produces the following output.

Data Type	Operation	Block Output
<ul style="list-style-type: none"> <li>• Fixed point</li> <li>• Boolean</li> <li>• Built-in integer</li> </ul>	isInf	FALSE
	isNaN	FALSE
	isFinite	TRUE

## Rules for Data Type Propagation

The following rules apply for data type propagation when your block has one or more input ports with unspecified data types.

When the block is in...	And...	The block uses...
Two-input mode	Both input ports have unspecified data types	<code>double</code> as the default data type for both inputs
	One input port has an unspecified data type	The data type from the specified input port as the default data type of the other port
One-input mode	The input port has an unspecified data type	<code>double</code> as the default data type for the input

## Data Type Support

The Relational Operator block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For two-input mode, one input can be real and the other complex when the operator is `==` or `~=`. Complex inputs work only for `==`, `~=`, `isInf`, `isNaN`, and `isFinite`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Show data type assistant

Display the **Data Type Assistant**.

#### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

## Relational operator

Specify the operation for comparing two inputs or determining the signal type of one input.

### Settings

**Default:** <=

==

TRUE if the first input is equal to the second input

~=

TRUE if the first input is not equal to the second input

<

TRUE if the first input is less than the second input

<=

TRUE if the first input is less than or equal to the second input

>=

TRUE if the first input is greater than or equal to the second input

>

TRUE if the first input is greater than the second input

isInf

TRUE if the input is Inf

isNaN

TRUE if the input is NaN

isFinite

TRUE if the input is finite

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

**Default:** On

On  
Enable zero-crossing detection.

Off  
Do not enable zero-crossing detection.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Require all inputs to have the same data type

Require that all inputs have the same data type.

### Settings

**Default:** Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

### Dependency

This check box is not available when you select `isInf`, `isNaN`, or `isFinite` for **Relational operator**, because the block is in one-input mode.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output data type

Specify the output data type.

### Settings

**Default:** boolean

**Inherit:** Logical (see Configuration Parameters: Optimization)

Uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

---

**Note:** This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

---

`boolean`

Specifies output data type is `boolean`.

`fixdt(1,16)`

Specifies output data type is `fixdt(1,16)`.

`<data type expression>`

Uses the name of a data type object, for example, `Simulink.NumericType`.

---

**Tip:** To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

---

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Mode

Select the category of data to specify.

### Settings

**Default:** Built in

#### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables **Logical** (see **Configuration Parameters: Optimization**).

#### Built in

Specifies built-in data types. Selecting **Built in** enables **boolean**.

#### Fixed point

Specifies fixed-point data types.

#### Expression

Specifies expressions that evaluate to data types.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Integer

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0.

### Command-Line Information

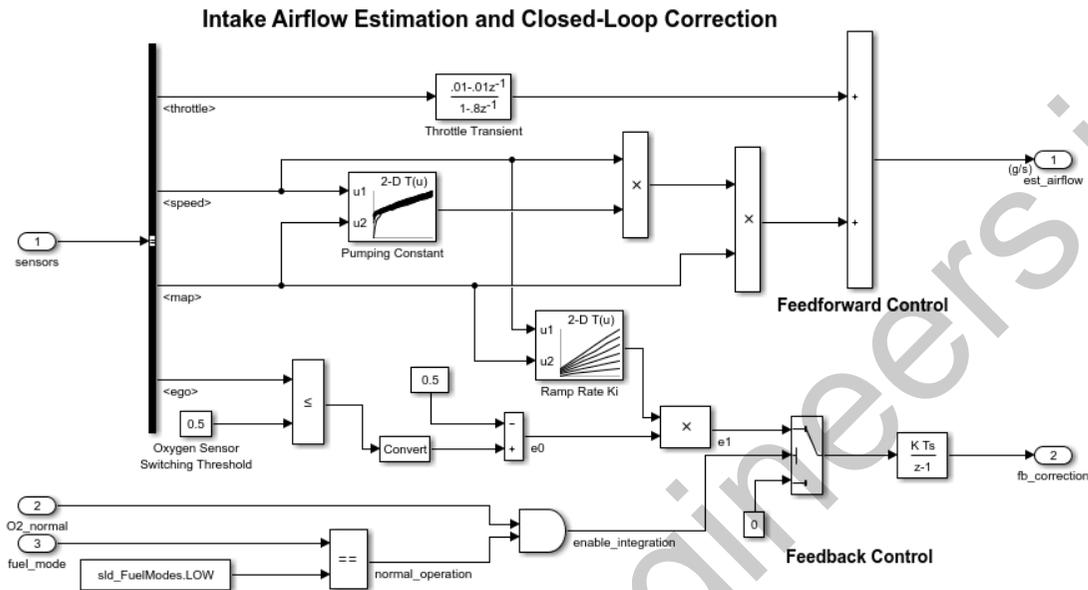

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Examples

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses two Relational Operator blocks:

Both Relational Operator blocks operate in two-input mode.

The block that uses this operator...	Compares...
<=	The value of the oxygen sensor to the threshold value, 0.5
==	The value of the fuel mode to the ideal value, sld_FuelModes.LOW

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes

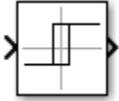

Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

**Introduced before R2006a**

controlengineers.ir

## Relay

Switch output between two constants

## Library

Discontinuities

## Description

The Relay block allows its output to switch between two specified values. When the relay is on, it remains on until the input drops below the value of the **Switch off point** parameter. When the relay is off, it remains off until the input exceeds the value of the **Switch on point** parameter. The block accepts one input and generates one output.

The **Switch on point** value must be greater than or equal to the **Switch off point**. Specifying a **Switch on point** value greater than the **Switch off point** models hysteresis, whereas specifying equal values models a switch with a threshold at that value.

---

**Note:** When the initial input falls *between* the **Switch off point** and **Switch on point** values, the initial output is the value when the relay is off.

---

## Data Type Support

The Relay block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

- Boolean
- Enumerated (output only)

If **Output when on** or **Output when off** is an enumerated value, both must be of the same enumerated type as the output.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

The **Main** pane of the Relay block dialog box appears as follows:

### Switch on point

The “on” threshold for the relay. The **Switch on point** parameter is converted to the input data type offline using round-to-nearest and saturation.

### Switch off point

The “off” threshold for the relay. The **Switch off point** parameter is converted to the input data type offline using round-to-nearest and saturation.

### Output when on

The output when the relay is on.

### Output when off

The output when the relay is off.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

---

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

---

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input **u**. All other input signals must be sample based.

Input Signal <b>u</b>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

#### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

#### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

#### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`
- An enumerated data type, for example, `Enum:BasicColors`

In this case, **Output when on** and **Output when off** must be of the same enumerated type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in Simulink User's Guide for more information.

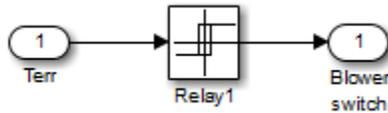

**Lock output data type setting against changes by the fixed-point tools**

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

**Examples**

The `sldemo_househeat` model shows how you can use the Relay block.

The Relay block appears in the Thermostat subsystem.

The thermostat allows fluctuations of 5 degrees Fahrenheit above or below the desired room temperature. If air temperature drops below 65 degrees Fahrenheit, the thermostat turns on the heater. The Relay block outputs a value of 1 to turn on the heater and a value of 0 to turn off the heater.

**Characteristics**

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

**Introduced before R2006a**

## Repeating Sequence

Generate arbitrarily shaped periodic signal

### Library

Sources

### Description

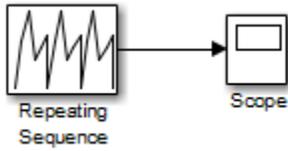

The Repeating Sequence block outputs a periodic scalar signal having a waveform that you specify using the **Time values** and **Output values** parameters. The **Time values** parameter specifies a vector of output times. The **Output values** parameter specifies a vector of signal amplitudes at the corresponding output times. Together, the two parameters specify a sampling of the output waveform at points measured from the beginning of the interval over which the waveform repeats (the period of the signal).

By default, both parameters are [0 2]. These default settings specify a sawtooth waveform that repeats every 2 seconds from the start of the simulation and has a maximum amplitude of 2.

### Algorithm

The block sets the input period as the difference between the first and last value of the **Time values** parameter. The output at any time  $t$  is the output at time  $t = t - n \cdot \text{period}$ , where  $n$  is an integer. The sequence repeats at  $t = n \cdot \text{period}$ . The block uses linear interpolation to compute the value of the waveform between the output times that you specify.

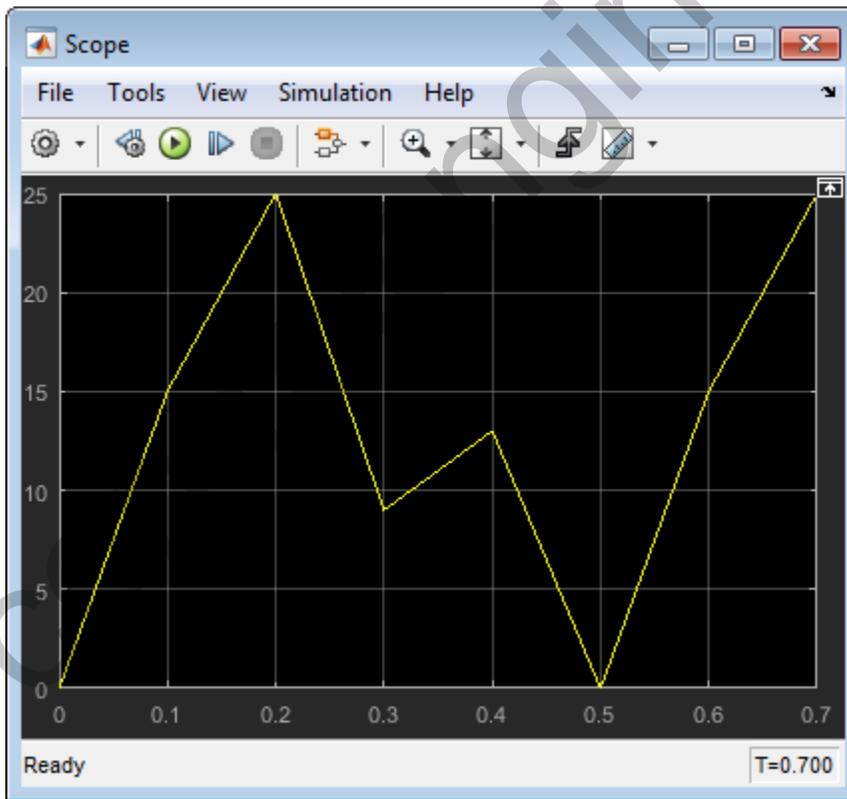

In the following model, the Repeating Sequence block defines **Time values** as [0:0.1:0.5] and **Output values** as [0 15 25 09 13 17]. The stop time of the simulation is 0.7 second.

For the Repeating Sequence block:

- The input period is 0.5.
- The output at any time  $t$  is the output at time  $t = t - 0.5n$ , where  $n = 0, 1, 2$ , and so on.
- The sequence repeats at  $t = 0.5n$ , where  $n = 0, 1, 2$ , and so on.

When you run the model, you get the following results:

At  $t = 0.5$ , the expected output is equal to the output at  $t = 0$ , which is 0. Therefore, the last value in the **Output values** vector [0 15 25 09 13 17] does not appear.

## Data Type Support

The Repeating Sequence block outputs real signals of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Time values

Specify a vector of strictly monotonically increasing time values. The default is [0 2].

### Output values

Specify a vector of output values. Each element corresponds to the time value in the same column. The default is [0 2].

## Examples

The following Simulink examples show how to use the Repeating Sequence block:

- sldemo\_fuelsys
- sldemo\_hydrod
- sldemo\_VariableTransportDelay

## Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	No

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Repeating Sequence Interpolated

Output discrete-time sequence and repeat, interpolating between data points

## Library

Sources

## Description

The Repeating Sequence Interpolated block outputs a discrete-time sequence and then repeats it. Between data points, the block uses the method you specify for the **Lookup Method** parameter to determine the output.

## Data Type Support

The Repeating Sequence Interpolated block outputs signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

Vector of output values

Specify the column vector containing output values of the discrete time sequence.

### **Vector of time values**

Specify the column vector containing time values. The time values must be strictly increasing, and the vector must have the same size as the vector of output values.

### **Lookup Method**

Specify the lookup method to determine the output between data points.

### **Sample time**

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

### **Output minimum**

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### **Output maximum**

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### **Output data type**

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Repeating Sequence, Repeating Sequence Stair

Introduced before R2006a

## Repeating Sequence Stair

Output and repeat discrete time sequence

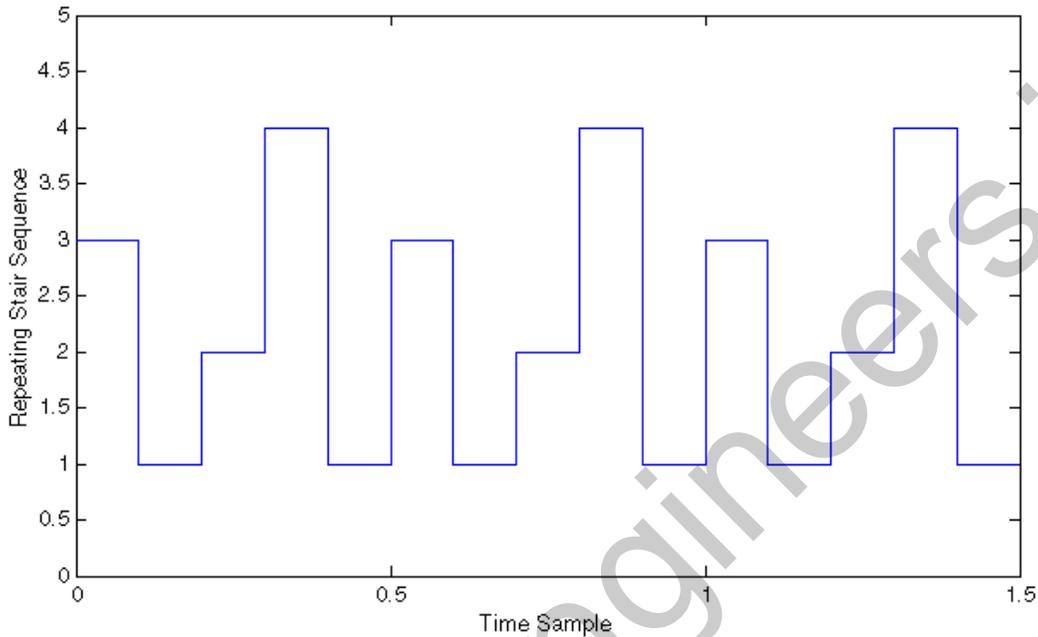

### Library

Sources

### Description

The Repeating Sequence Stair block outputs and repeats a stair sequence that you specify with the **Vector of output values** parameter. For example, you can specify the vector as `[3 1 2 4 1]'`, which produces the following stair sequence:

## Data Type Support

The Repeating Sequence Stair block outputs signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

**Vector of output values**

Specify the vector containing values of the repeating stair sequence.

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`

- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter

## Reset

Add reset port to subsystem

## Library

Ports & Subsystems

## Description

A Reset block is the control port for a resettable subsystem, and it determines when the subsystem states reset to their initial condition. Resettable subsystems contain a Reset block at their root level.

A resettable subsystem resets the blocks inside it when a trigger occurs at the reset port, similar to the reset port of a block. The reset event initializes the states of blocks inside a resettable subsystem to their initial conditions. For more information, see “Resettable Subsystems”.

## Data Type Support

The Reset block accepts signals of Simulink numeric and Boolean data types. It also accepts fixed-point signals of type ufix1. For more information, see “Data Types Supported by Simulink”.

## Parameters

### Reset trigger type

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

### Settings

Default: rising

rising

Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.

falling

Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.

either

Reset the state when the reset signal changes from a zero to a nonzero value or changes sign.

level

Reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

level hold

Reset the state when the reset signal is nonzero at the current time step.

## Propagate sizes of variable-size signals

Specify when to propagate a variable-size signal.

### Settings

**Default:** Only when resetting

Only when resetting

Propagates variable-size signals only when resetting the resettable subsystem. When you select this option, sample time must be periodic.

During execution

Propagates variable-size signals at each time step.

## Enable zero-crossing detection

Select this check box to enable zero-crossing detection.

### Settings

**Default:** On

- On  
Detect zero crossings.
- Off  
Do not detect zero crossings.

## Characteristics

Sample Time	Determined by the signal at the reset port
Dimensionalized	Yes
Virtual	No
Zero-Crossing Detection	Yes, if enabled

## See Also

### See Also

“Resettable Subsystems”

Introduced in R2015a

## Reset Function

Executes contents on a model reset event

**Library:** User-Defined Functions

## Description

The Reset Function block is a preconfigured subsystem block created from an Initialize block that executes on a model reset event.

---

**Note:** The Reset Function block is not in the Simulink Library Browser.

---

To create a Reset Function block:

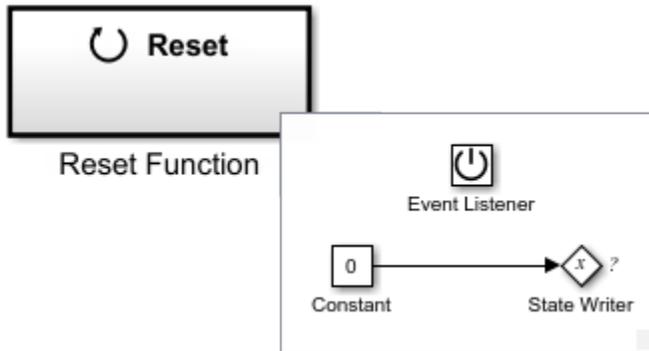

- 1 Add an Initialize block.
- 2 Open the Event Listener block within the Initialize block. From the **Event** drop-down list, select **Reset**.

One parameter appears.

- By default, the **Event name** is set to **Reset**. You can change the name of a reset event by editing this text box.

- 3 Rename the block from **Initialize Function** to **Reset Function**.

The Reset Function block includes an Event Listener block with **Event** set to **Reset**, a Constant block with **Constant value** set to 0, and a State Writer block.

Replace the Constant block with source blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

A model can potentially have multiple Reset Function blocks with each block having a different **Event name**. Each of these reset events appear in the generated code as a different function.

## Resettable Delay

Delay input signal by variable sample period and reset with external signal

## Library

Discrete

## Description

The Resettable Delay block is a variant of the **Delay** block that has the source of the initial condition set to **Input port** and the external reset algorithm set to **Rising**, by default.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

## See Also

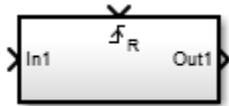

### See Also

Introduced in R2012b

# Resettable Subsystem

Represent subsystem whose states reset with external trigger

## Library

Ports & Subsystems

## Description

This block is preconfigured as a starting point for a resettable subsystem. For more information, see “Resettable Subsystems”.

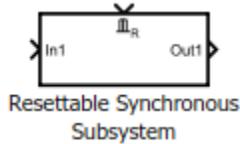

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

Introduced in R2015a

## Resettable Synchronous Subsystem

Represent resettable subsystem that has synchronous reset and enable behavior

### Library

HDL Coder / HDL Subsystems

### Description

The Resettable Synchronous Subsystem block uses the **Synchronous** mode of the State Control block with the Resettable Subsystem block. If an **S** symbol appears in the subsystem, then it is synchronous. For more information about the block in HDL Coder, see Resettable Synchronous Subsystem.

For more information about the State Control block, see State Control.

### Data Type Support

See **Inport** for information on the data types accepted by a subsystem's input ports. See **Outputport** for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

#### Show port labels

Display subsystem port labels on the subsystem block.

## Settings

### Default: FromPortIcon

none

Does not display port labels on the subsystem block.

### FromPortIcon

If the corresponding port icon displays a signal name, the parameter displays the signal name on the subsystem block. Otherwise, it displays the port block name.

### FromPortBlockName

Display the name of the corresponding port block on the subsystem block.

### SignalName

If the signal connected to the subsystem block port is named, this parameter displays the name. Otherwise, it displays the name of the corresponding port block.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Read/Write permissions

Control user access to the contents of the subsystem.

### Settings

**Default:** ReadWrite

#### ReadWrite

Enables opening and modification of subsystem contents.

#### ReadOnly

Enables the opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem, and create and modify local copies of the subsystem. You cannot change the permissions or modify the contents of the original library instance.

#### NoReadOrWrite

Disables the opening or modification of subsystem. If the subsystem resides in a block library, you can create links to the subsystem in a model. You cannot open, modify, change permissions, or create local copies of the subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Name of error callback function

Enter the name of the function to be called if an error occurs while Simulink software is executing the subsystem.

### Settings

**Default:** ' '

Simulink passes two arguments to the function: the subsystem handle and a character vector that specifies the error type. If no function is specified, you get a generic error message.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

### Settings

**Default:** All

#### All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, Simulink.Signal objects).

#### ExplicitOnly

Resolve the names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked by using the signal resolution icon.

#### None

Do not resolve any workspace variable names.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as atomic unit

Causes Simulink to treat the subsystem as a unit when determining the execution order of block methods.

### Settings

**Default:** Off

On

Cause Simulink to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause the execution of block methods in the subsystem to be interleaved with the execution of block methods outside the subsystem.

### Dependencies

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-1779.
- “Sample time (-1 for inherited)” on page 1-1782
- “Function packaging” on page 1-1784 (requires a Simulink Coder license)

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

### Settings

**Default:** On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

### Settings

**Default:** Auto

Auto

Simulink Coder chooses the optimal format based on the type and number of subsystem instances in the model.

Inline

Simulink Coder inlines the subsystem unconditionally.

Nonreusable function

Simulink Coder explicitly generates a separate function in a separate file. In some cases, when you apply this setting, the subsystems generate functions with

arguments that depend on the “Function interface” on page 1-1793 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-1788 and “File name (no extension)” on page 1-1791. These functions are not reentrant.

### Reusable function

Simulink Coder generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy. In this case, the subsystem must be in a library.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus

Introduced in R2016b

# Reshape

Change dimensionality of signal

## Library

Math Operations

## Description

The Reshape block changes the dimensionality of the input signal to a dimensionality that you specify, using the block's **Output dimensionality** parameter. For example, you can use the block to change an N-element vector to a 1-by-N or N-by-1 matrix signal, and vice versa.

The **Output dimensionality** parameter lets you select any of the following output options.

Output Dimensionality	Description
1-D array	Converts a multidimensional array to a vector (1-D array) array signal. The output vector consists of the first column of the input matrix followed by the second column, etc. (This option leaves a vector input unchanged.)
Column vector	Converts a vector, matrix, or multidimensional input signal to a column matrix, i.e., an M-by-1 matrix, where M is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Row vector	Converts a vector, matrix, or multidimensional input signal to a row matrix, i.e., a 1-by-N matrix where

Output Dimensionality	Description
	N is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Customize	Converts the input signal to an output signal whose dimensions you specify, using the <b>Output dimensions</b> parameter. The value of the <b>Output dimensions</b> parameter can be a one- or multi-element vector. A value of [N] outputs a vector of size N. A value of [M N] outputs an M-by-N matrix. The number of elements of the input signal must match the number of elements specified by the <b>Output dimensions</b> parameter. For multidimensional arrays, the conversion is done along the first dimension.
Derive from reference input port	Creates a second input port, Ref, on the block. Derives the dimensions of the output signal from the dimensions of the signal input to the Ref input port. Selecting this option disables the <b>Output dimensions</b> parameter. When you select this parameter, the input signals for both inport ports, U and Ref, must have the same sampling mode (sample-based or frame-based).

## Data Type Support

The Reshape block accepts and outputs signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types.

For more information, see “Data Types Supported by Simulink”.

You can use an array of buses as an input signal to a Reshape block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Parameters

### Output dimensionality

Specify the dimensionality of the output signal.

## Output dimensions

Specify a custom output dimensionality. This parameter is available only when you set **Output dimensionality** to **Customize**.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

# Rocker Switch

Set on/off values to tune parameters or variables

## Library

Dashboard

## Description

The Rocker Switch block enables you to control tunable parameters and variables in your model during simulation. The block has two states that can be set to two different values.

To control a tunable parameter or variable using the Rocker Switch block, double-click the Rocker Switch block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

## Limitations

The Rocker Switch block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

Limitation	Workaround
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### States

Switch values and labels.

### Settings

**Default Labels:** Off and On

**Default Values:** 0 and 1

By default, the **Off** state label corresponds to the set value of 0, and the **On** state label corresponds to the set value of 1.

The state labels appear on the outside of the switch. You can change the state labels to another character vector. You can change the state values to any real value that is between negative `realmax` and positive `realmax`.

## Label

Position of the block label or instructional text if the block is not connected.

### Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

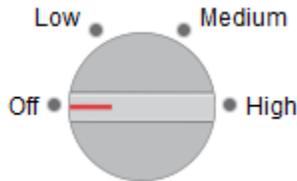

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Rotary Switch

Set value on dial switch to tune parameters or variables

## Library

Dashboard

## Description

The Rotary Switch block enables you to control tunable parameters and variables in your model during simulation.

To control a tunable parameter or variable using the Rotary Switch block, double-click the Rotary Switch block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

The state values determine the discrete values generated for the tunable parameter or variable. You can modify the states by editing the **State Value** and **State Label** in the **States** table.

## Limitations

The Rotary Switch block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

Limitation	Workaround
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### States

The state values determine the discrete values generated for the tunable parameter or variable. You can modify the states by editing the **State Value** and **State Label** in the **States** table.

To add a state, click **+**, and enter the **State Value** and **State Label**.

To remove a state, select the state in the table, and click -.

## Label

Position of the block label or instructional text if the block is not connected.

## Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

## Rounding Function

Apply rounding function to signal

### Library

Math Operations

### Description

The Rounding Function block applies a rounding function to the input signal to produce the output signal.

You can select one of the following rounding functions from the **Function** list:

- floor

Rounds each element of the input signal to the nearest integer value towards minus infinity.

- ceil

Rounds each element of the input signal to the nearest integer towards positive infinity.

- round

Rounds each element of the input signal to the nearest integer.

- fix

Rounds each element of the input signal to the nearest integer towards zero.

The name of the selected function appears on the block.

The input signal can be a scalar, vector, or matrix signal having real- or complex-valued elements of type `double`. The output signal has the same dimensions, data type, and numeric type as the input. Each element of the output signal is the result of applying the selected rounding function to the corresponding element of the input signal.

---

**Tip:** Use the Rounding Function block instead of the `Fcn` block when you want vector or matrix output, because the `Fcn` block produces only scalar output.

Also, the Rounding Function block provides two more rounding modes. The `Fcn` block supports `floor` and `ceil`, but does not support `round` and `fix`.

---

## Data Type Support

The Rounding Function block accepts and outputs real signals of type `double` or `single`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Function

Specify the rounding function.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Characteristics

Data Types	Double   Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes

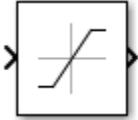

Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

Controlengineers.ir

## Saturation

Limit range of signal

## Library

Discontinuities

## Description

The Saturation block imposes upper and lower limits on an input signal.

When the input is...	Where...	The block output is the...
Within the range specified by the <b>Lower limit</b> and <b>Upper limit</b> parameters	$\text{Lower limit} \leq \text{Input value} \leq \text{Upper limit}$	Input value
Less than the <b>Lower limit</b> parameter	$\text{Input value} < \text{Lower limit}$	Lower limit
Greater than the <b>Upper limit</b> parameter	$\text{Input value} > \text{Upper limit}$	Upper limit

When the **Lower limit** and **Upper limit** parameters have the same value, the block output is that value.

## Data Type Support

The Saturation block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Show data type assistant

Display the **Data Type Assistant**.

#### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

## Upper limit

Specify the upper bound on the input signal.

### Settings

**Default:** 0.5

**Minimum:** value from the **Output minimum** parameter

**Maximum:** value from the **Output maximum** parameter

### Tip

- When the input signal to the Saturation block is above this value, the output of the block is clipped to this value.
- The **Upper limit** parameter is converted to the output data type offline using round-to-nearest and saturation.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Lower limit

Specify the lower bound on the input signal.

### Settings

**Default:** -0.5

**Minimum:** value from the **Output minimum** parameter

**Maximum:** value from the **Output maximum** parameter

### Tips

- When the input signal to the Saturation block is below this value, the output of the block is clipped to this value.
- The **Lower limit** parameter is converted to the output data type offline using round-to-nearest and saturation.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as gain when linearizing

Select this parameter to cause the linearization commands to treat the gain as 1.

### Settings

**Default:** On

On

Select to cause the linearization commands to treat the gain as 1.

Off

Clear to cause the linearization commands to treat the gain as 0.

### Tips

Linearization commands in Simulink software treat this block as a gain in state space.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

**Default:** On

On

Enable zero-crossing detection.

Off

Do not enable zero-crossing detection.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Same as input

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**Inherit:** Same as input

Use data type of input signal.

**double**

Output data type is double.

**single**

Output data type is single.

**int8**

Output data type is int8.

**uint8**

Output data type is uint8.

**int16**

Output data type is int16.

**uint16**

Output data type is uint16.

**int32**

Output data type is int32.

**uint32**

Output data type is uint32.

**fixdt(1,16,0)**

Output data type is fixed point fixdt(1,16,0).

**fixdt(1,16,2<sup>0</sup>,0)**

Output data type is fixed point fixdt(1,16,2<sup>0</sup>,0).

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via back propagation
- Same as input (default)

##### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Fixed-point data types.

##### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

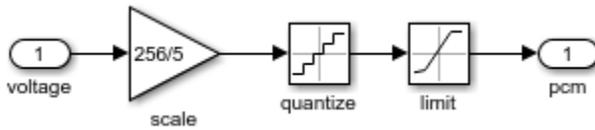

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Examples

The `sldemo_boiler` model shows how you can use the Saturation block.

The Saturation block appears in the Boiler Plant model/digital thermometer/ADC subsystem.

The ADC subsystem digitizes the input analog voltage by:

- Multiplying the analog voltage by 256/5 with the **Gain** block
- Rounding the value to integer floor with the **Quantizer** block
- Limiting the output to a maximum of 255 (the largest unsigned 8-bit integer value) with the **Saturation** block

For more information, see “Explore the Fixed-Point "Bang-Bang Control" Model” (Stateflow) in the Stateflow documentation.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

Saturation Dynamic

Introduced before R2006a

## Saturation Dynamic

Bound range of input

## Library

Discontinuities

## Description

The Saturation Dynamic block bounds the range of an input signal to upper and lower saturation values. An input signal outside of these limits saturates to one of the bounds where:

- The input below the lower limit is set to the lower limit.
- The input above the upper limit is set to the upper limit.

The input for the upper limit is the **up** port, and the input for the lower limit is the **lo** port.

## Data Type Support

The Saturation Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

---

**Tip:** Although this block accepts Boolean signals, avoid this usage.

---

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Output minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as second input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code.  You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an

Action	Reasons for Taking This Action	What Happens for Overflows	Example
			unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point

## Scope

Display signals generated during simulation

## Description

The Simulink Scope block displays time domain signals with respect to simulation time.

Input signal characteristics:

- **Signal** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Signal data type** — Any data type that Simulink supports including real, complex, fixed-point, and enumerated data types. See “Data Types Supported by Simulink”. You can use a nonvirtual bus or array of buses signal as the input signal. See “Bus Support” on page 1-1539.
- **Signal dimension** — Scalar, one-dimensional (vector), two dimensional (matrix), or multidimensional. Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Scope display features:

- **Simulation control** — Debug models from a Scope window using Run, Step Forward, and Step Backward toolbar buttons.
- **Multiple signals** — Plot multiple signals on the same  $y$ -axis (display) using multiple input ports.
- **Multiple  $y$ -axes (displays)** — Display multiple  $y$ -axes. All of the  $y$ -axes have a common time range on the  $x$ -axis.
- **Modify parameters** — Modify scope parameter values before and during a simulation.
- **Axis autoscaling** — During or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- **Display data after simulation** — If a Scope is closed at the start of a simulation, scope data is still written to the scope during a simulation. As a result, if you open

the Scope after a simulation, the Scope displays simulation results for attached input signals.

Oscilloscope features:

- **Triggers** — Set triggers to sync repeating signals and pause the display when events occur.
- **Data analysis** — Measure time and value differences between two signal data points. If you have a DSP System Toolbox™ license, measure signal characteristics including signal statistics, transitions, and peaks.

---

**Note:** Do not use Scope blocks in a Library. If you place a Scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the Scope window.

To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.

---

---

**Note:** Scope block may plot a single point when connected to a constant signal.

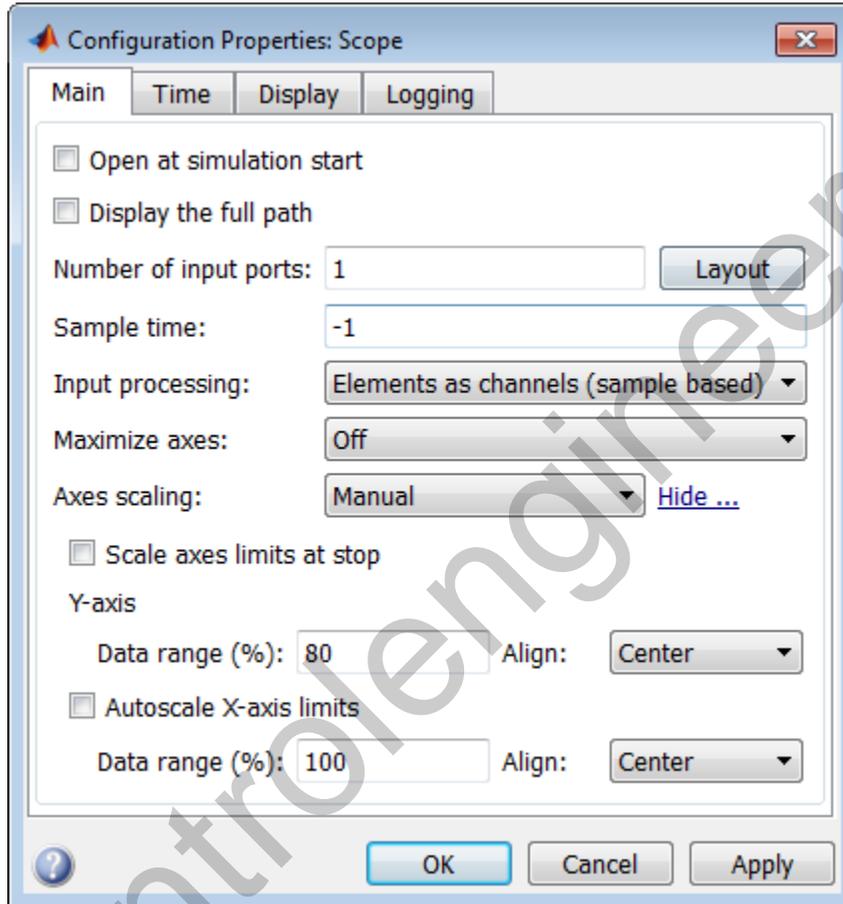

---

---

**Note:** For information on controlling a Scope programmatically, see “Control Scopes Programmatically” in the Simulink documentation.

---

## Configuration Properties

### Open at simulation start

Specify when a Scope window opens.

#### Settings

**Default:** Clear for Scope block. Select for Time Scope block.

Select

Open Scope window when simulation starts.

Clear

Do not open a closed Scope at the start of a simulation.

Scope Configuration property: `OpenAtSimulationStart`.

## Display the full path

Display full block path on Scope title bar.

### Settings

**Default:** Clear

Select

Display block path and name.

Clear

Display block name.

Scope Configuration property: No corresponding property.

## Number of input ports

Specify number of input ports on a Scope block, specified by an integer. Maximum number of input ports is 96. This property does not apply to floating scopes and scope viewers.

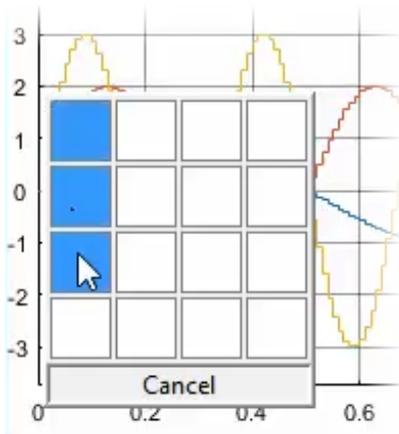

**Default:** 1

Scope Configuration property: `NumInputPorts`.

## Layout button

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

- If the number of displays are equal to the number of ports, signals from each port appear on separate displays.
- If the number of displays are less than the number of ports, signals from additional ports appear on the last display.
- For layouts with multiple columns and rows, ports are mapped down then across.

### Settings

**Default:** 1

Scope Configuration property: `LayoutDimensions`.

### Sample time

Specify time interval between Scope block updates during a simulation, specified as a positive real number. This property does not apply to floating scopes and scope viewers.

### Settings

**Default:** -1 for inherited

Scope Configuration property: `SampleTime`.

### Input processing

Specify sample-based or frame-based processing of signals.

### Settings

**Default:** Elements as channels (sample based) for Scope block. Columns as channels (frame based) for Time Scope block.

Elements as channels (sample based)

Process signal values in a channel at each time interval.

Columns as channels (frame based)

Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Scope Configuration property: `FrameBasedProcessing`.

### Maximize axes

Maximize size of signal plots. Each of the plots expands to fit the full display. Maximizing the size of signal plots removes the background area around the plots.

### Settings

**Default:** Off for Scope block. Auto for Time Scope block.

Auto

If **Title** and **Y-label** properties are not specified, maximize all plots.

On

Maximize all plots. Values in **Title** and **Y-label** are hidden.

Off

Do not maximize plots.

Scope Configuration property: `MaximizeAxes`.

### Axes scaling

Specify when to scale y-axis to display all signal values.

### Settings

**Default:** Manual

## Manual

Manually scale y-axis range with **Scale Y-axis Limits** toolbar button.

## Auto

Scale y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box.

If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to **Auto** and clear the **Do not allow Y-axis limits to shrink** check box.

## After N Updates

Scale y-axis after the number of time steps specified in the Number of updates text box. Scaling occurs once during each run.

## Dependency

If this property is set to **After N Updates**, also specify the property **Number of updates**.

Scope Configuration property: **AxesScaling**.

## Do not allow Y-axis limits to shrink

Specify when y-axis range limits can change.

## Settings

**Default:** Select

Select

Allow y-axis range limits to increase but not decrease during a simulation.

Clear

Allow y-axis range limits to increase and decrease.

## Dependency

Click the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to **Auto** to display this property.

## Number of updates

Specify the number of updates that occur during a simulation before a Scope scales the y-axes, specified as an integer.

### Settings

**Default:** 10

### Dependency

Display and activate this property by clicking the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to After N Updates.

Scope Configuration property: AxesScalingNumUpdates.

## Scale axes limits at stop

Specify when to scale axes.

### Settings

**Default:** Select

- Select  
Scale axes when simulation stops.
- Clear  
Always scale axes.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

The y-axis limits are always scaled. The x-axis limits are scaled only if you also select the **Autoscale X-axis limits** check box.

## Y-axis Data range (%)

Specify percentage of y-axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire y-axis range.

## Settings

**Default:** 80

Values are 1 through 100.

## Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

## Y-axis Align

Specify where to align plotted data along the  $y$ -axis data range when **Y-axis Data range** is set to less than 100 percent.

## Settings

**Default:** Center

Top

Align signals with maximum values at top of  $y$ -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of  $y$ -axis range.

## Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

## Autoscale X-axis limits

Scale  $x$ -axis range limits when scaling axes.

## Settings

**Default:** Clear

Select

Scale  $x$ -axis range to fit all signal values. If **Axes scaling** is set to **Auto**, scales the data currently within the axes, not the entire signal in the data buffer.

Clear

Do not scale  $x$ -axis range.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### X-axis Data range (%)

Specify percentage of  $x$ -axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire  $x$ -axis range.

### Settings

**Default:** 100

Values are 1 through 100.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### X-axis Align

Specify where to align plotted data along the  $x$ -axis when **X-axis Data range** is set to less than 100 percent.

### Settings

**Default:** Center

Top

Align signals with maximum values at top of  $x$ -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of  $x$ -axis range.

### Dependency

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

### Time span

Specify length of  $x$ -axis range to display.

The block calculates the beginning and end times of the time range using the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

### Settings

**Default:** Auto

Auto

Difference between the simulation start and stop times.

User defined

Value less than the total simulation time.

Scope Configuration property: `TimeSpan`.

### Time span overrun action

Specify how to display data beyond the visible  $x$ -axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

### Settings

**Default:** Wrap

Wrap

Draw a full screen of data from left to right, clear the screen, and then restart drawing of data.

Scroll

Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Scope Configuration property: `TimeSpanOverrunAction`.

## Time units

Specify units to display on the  $x$ -axis.

### Settings

**Default:** `None` for Scope block. `Metric` for Time Scope block.

#### Metric

Display time units based on the length of **Time span**.

#### Seconds

Display Time (seconds).

#### None

Do not display time units.

Scope Configuration property: `TimeUnits`.

## Time display offset

Offset the  $x$ -axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scaler or vector.

- Scaler — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

### Settings

**Default:** `0`

Scope Configuration property: `TimeDisplayOffset`.

## Time-axis labels

Specify how  $x$ -axis (time) labels display.

## Settings

**Default:** Bottom Displays Only for Scope block. All for Time Scope block.

All

Display  $x$ -axis labels on all  $y$ -axes.

None

Do not display labels. Selecting **None** also clears the **Show time-axis label** check box.

Bottom Displays Only

Display  $x$ -axis label on the bottom  $y$ -axis.

## Dependency

Set **Active display** before setting this property. Activate this property by selecting **Show time-axis label** and setting **Maximize axes** to off.

Scope Configuration property: TimeAxisLabels.

## Show time-axis label

Display or hide  $x$ -axis (time) labels.

## Settings

**Default:** Clear for Scope block. Select for Time Scope block.

Select

Display  $x$ -axis label for the active display

Clear

Hide  $x$ -axis labels.

## Dependency

Set **Active display** before setting this property. If you select this property and set the **Time-axis labels** is set to **NONE**, this property is deactivated.

Scope Configuration property: ShowTimeAxisLabel.

## Active display

Display for setting display-specific properties, specified as a positive integer. The number of a display corresponds to its column-wise placement index.

### Settings

**Default:** 1

### Dependency

Setting this property selects the display for setting the properties **Show Grid**, **Show legend**, **Title**, **Plot signals as magnitude and phase**, **Y-label**, and **Y-Limits**.

Scope Configuration property: `ActiveDisplay`.

### Title

Specify a title for display, specified as a character vector. The default value `%<SignalLabel>` uses the input signal name for the title.

### Settings

**Default:** `%<SignalLabel>`

### Dependency

Set **Active display** before setting this property.

Scope Configuration property: `Title`.

## Show legend

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

### Settings

**Default:** Clear

Select

Display signal legend. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

Clear

Hide signal legend.

### Dependency

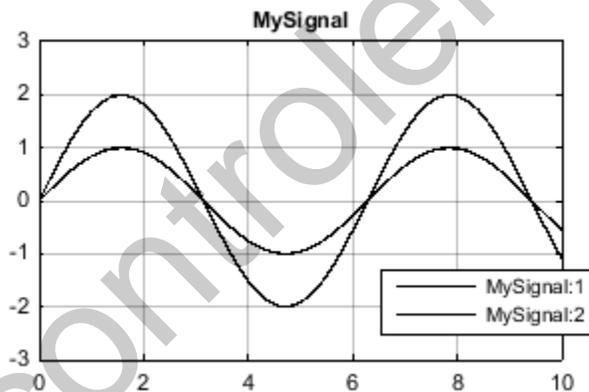

Set **Active Display** before setting this property.

Scope Configuration property: **ShowLegend**.

### Example

Connect a Sine Wave block to a Scope. Set the **Amplitude** parameter for the Sine Wave to [1 2]. Select the **Legends** check box for the Scope. Set the **Signal name** property for the signal to MySignal.

After simulating this model, the Scope window displays a sine wave for the two signal channels in MySignal, MySignal:1, and MySignal:2.

Edit the name of any channel in the legend by double-clicking the current name and entering a new channel name.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

See also “Signal Dimensions” and “Determine Output Signal Dimensions”.

## Show grid

Show vertical and horizontal grid lines.

### Settings

**Default:** Select

- Select  
Display grid lines.
- Clear  
Hide grid lines.

### Dependency

Set **Active Display** before setting this property.

Scope Configuration property: ShowGrid.

## Plot signals as magnitude and phase

Split display into magnitude and phase plots.

### Settings

**Default:** Clear

- Select  
Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values.
- Clear  
Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

### Dependency

Set **Active Display** before setting this property.

Scope Configuration property: PlotAsMagnitudePhase.

## Y-limits (Minimum)

Specify minimum value of  $y$ -axis, specified as real number.

### Settings

**Default:** -10

### Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The  $y$ -axis limits of the phase plot are always [ -180 180].

Scope Configuration property: YLimits.

## Y-limits (Maximum)

Specify maximum value of  $y$ -axis, specified as real number.

### Settings

**Default:** +10

### Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The  $y$ -axis limits of the phase plot are always [ -180 180].

Scope Configuration property: YLimits.

## Y-label

Specify  $y$ -axis label, specified as a character vector.

To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals. For example, if you have a signal for velocity with units of m/S. enter

Velocity (%<SignalUnits>)

## Settings

**Default:** No label for Scope block. **Amplitude** for Time Scope block.

## Dependency

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** hides this property and plots are labeled **Magnitude** and **Phase**.

Scope Configuration property: `YLabel1`.

## Limit data points to last

Specify to limit buffered data values before plotting and saving signals.

## Settings

**Default:** Clear, 5000

### Select

Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

In some cases, for example where the sample time is small, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation. If a scope plots a portion of your signals, consider increasing the number of data values to save.

### Clear

Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

## Dependency

If this property is selected, also specify the number of data values by entering a positive integer in the text box. This property limits the data values a scope plots and the data

values saved in the MATLAB variable specified in **Variable name**. Data values are from the end of a simulation.

Scope Configuration properties: `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

## Decimation

Reduce the amount of scope data to display and save.

### Settings

**Default:** Clear, 2

Select

Plot and Log (save) scope data every Nth data point, where N is the decimation factor entered in the text box.

Clear

Save all scope data values.

### Dependency

If this property is selected, also specify the decimation factor by entering a positive integer in the text box. The scope buffers every Nth data point, where N is the decimation factor you specify. A value of 1 buffers all data values. This property limits the data values a scope plots and the data values saved in the MATLAB variable specified in **Variable name**.

## Log data to workspace

Activate saving scope data to a variable in the MATLAB workspace.

### Settings

**Default:** Clear

Select

Activate logging and activate the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

Clear

Inactivate logging and logging properties are unavailable.

### Dependency

If this property is selected, also specify the properties **Variable name** and **Save format**.

Scope Configuration property: **DataLogging**.

For a procedure showing how to save signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Floating Scope Block”.

### Variable name

Specify a variable name for saving scope data in the MATLAB workspace, specified as a character vector. This property does not apply to floating scopes and scope viewers.

### Settings

**Default:** ScopeData

### Dependency

Activate this property by selecting **Log data to workspace**.

Scope Configuration property: **DataLoggingVariableName**.

### Save format

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

### Settings

**Default:** Dataset

#### Dataset

Save data as a dataset object. This format does not support variable-size data, MAT-file logging, or external mode archiving. See `Simulink.SimulationData.Dataset`.

#### Structure With Time

Save data as a structure with associated time information.

#### Structure

Save data as a structure.

### Array

Save data as an array with associated time information. This format does not support variable-size data.

### Dependency

Activate this property by selecting **Log data to workspace**.

Scope Configuration property: DataLoggingSaveFormat.

### Style Properties

Open the Style dialog box:

- From the menu, select **View > Style**.
- From the Configuration Properties button arrow, select the Style button .

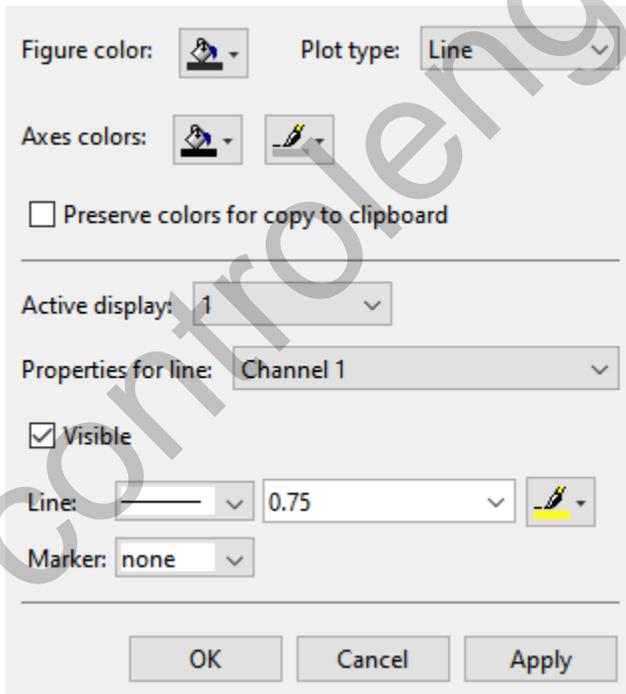

Figure color:  Plot type: Line   
 Axes colors:    
 Preserve colors for copy to clipboard  
 Active display: 1   
 Properties for line: Channel 1   
 Visible  
 Line:  0.75   
 Marker: none   
 OK Cancel Apply

### Figure color

Select background color for display.

### Plot type

Specify how to plot a signal.

**Default:** Auto for Scope block. Line for Time Scope block.

- Line — Line graph.
- Stairs — Stair-step graph.
- Stem — Stem graph.
- Auto — Line graph for continuous signals, a stair-step graph for discrete signals, and stem graph for Simulink message signals.

### Active display

Select active display for setting style properties.

**Default:** 1

### Axes colors

Select the background color for axes (displays) with the first color pallet. Select the grid and label color with the second color pallet.

### Preserve colors for copy to clipboard

Specify whether or not to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

**Default:** Off

### Properties for line

Select active line for setting line style properties.

## Visible

Plot signal on active display.

**Default:** Select

Select  
Plot signal.

Clear  
Hide signal.

## Line

Select line style, width, and color.

## Marker

Select marker style.

**Default:** None

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	No

## Bus Support

You can connect nonvirtual bus and array of buses signals to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log bus signals with a Scope block, set the **Save format** block parameter to Dataset.

# Second-Order Integrator, Second-Order Integrator Limited

Integrate input signal twice

## Library

Continuous

## Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\begin{aligned} \frac{d^2x}{dt^2} &= u, \\ \left. \frac{dx}{dt} \right|_{t=0} &= dx_0, \\ x|_{t=0} &= x_0, \end{aligned}$$

where  $u$  is the input to the system. The block is therefore a dynamic system with two continuous states:  $x$  and  $dx/dt$ .

---

**Note:** These two states have a mathematical relationship, namely, that  $dx/dt$  is the derivative of  $x$ . In order to satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

---

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1543.

Simulink software can use a number of different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “About Solvers”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states
- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize  $dx/dt$  when  $x$  reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

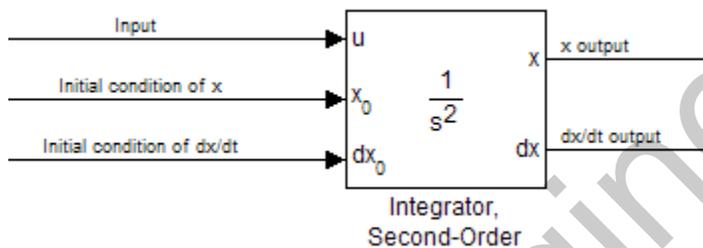

## Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state  $x$  as a block parameter, use the **Initial condition source  $x$**  drop-down menu to select **internal** and enter the value in the **Initial condition  $x$**  field.
- To provide the initial conditions from an external source for state  $x$ , specify the **Initial condition source  $x$**  parameter as **external**. An additional input port appears on the block.
- To define the initial conditions of state  $dx/dt$  as a block parameter, use the **Initial condition source  $dx/dt$**  drop-down menu to select **internal** and enter the value in the **Initial condition  $dx/dt$**  field.

- To provide the initial conditions from an external source for state  $dx/dt$ , specify **Initial condition source  $dx/dt$**  as external. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.

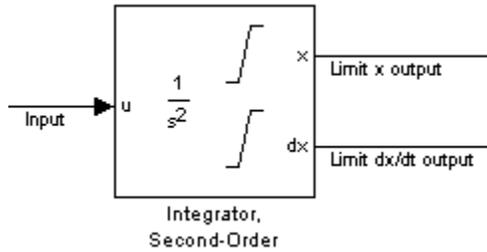

**Note:**

- Simulink does not allow initial condition values of `inf` or `NaN`.
- If you limit state  $x$  or state  $dx/dt$  by specifying saturation limits (see “Limiting the States” on page 1-1543) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.

**Limiting the States**

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position ( $x$ ). With the Second-Order Integrator block, you can limit the states  $x$  and  $dx/dt$  independent of each other. You can even change the limits during simulation; however, you cannot change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

The block appearance changes when you limit one or both states. Shown below is the appearance of the block with both states limited.

For each state, you can use the block parameter dialog box to set appropriate saturation limits.

### Limiting x only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state  $x$  on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.

Function Block Parameters: Integrator, Second-Order Limited

Second-Order Integrator  
Second-order continuous-time integration of the input signal.

x dx/dt Attributes

Initial condition source x: internal

Initial condition x:  
0.0

Limit x

Upper limit x:  
1

Lower limit x:  
0

Absolute tolerance x:  
auto

State name x:

OK Cancel Help Apply

The block then determines the values of the states as follows:

- When  $x$  is less than or equal to its lower limit, the value of  $x$  is held at its lower limit and  $dx/dt$  is set to zero.
- When  $x$  is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When  $x$  is greater than or equal to its upper limit, the value of  $x$  is held at its upper limit and  $dx/dt$  is set to zero.

You can choose to reinitialize  $dx/dt$  to a new value at the time when  $x$  reaches saturation. See “Reinitializing  $dx/dt$  when  $x$  reaches saturation” on page 1-1550

### Limiting $dx/dt$ only

As with state  $x$ , state  $dx/dt$  is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited parameter dialog box. You can manually set this parameter, **Limit dx/dt**, on the Second-Order Integrator block. In either case, you must enter the appropriate limits for  $dx/dt$ .

Function Block Parameters: Integrator, Second-Order Limited

Second-Order Integrator  
Second-order continuous-time integration of the input signal.

x dx/dt Attributes

Initial condition source dx/dt: internal

Initial condition dx/dt:  
0.0

Limit dx/dt

Upper limit dx/dt:  
inf

Lower limit dx/dt:  
-inf

Absolute tolerance dx/dt:  
auto

State name dx/dt:

OK Cancel Help Apply

If you limit only the state  $dx/dt$ , then the block determines the values of  $dx/dt$  as follows:

- When  $dx/dt$  is less than or equal to its lower limit, the value of  $dx/dt$  is held at its lower limit.
- When  $dx/dt$  is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When  $dx/dt$  is greater than or equal to its upper limit, the value of  $dx/dt$  is held at its upper limit.

When state  $dx/dt$  is held at its upper or lower limit, the value of  $x$  is governed by the first-order initial value problem:

$$\frac{dx}{dt} = L,$$

$$x(t_L) = x_L,$$

where  $L$  is the  $dx/dt$  limit (upper or lower),  $t_L$  is the time when  $dx/dt$  reaches this limit, and  $x_L$  is the value of state  $x$  at that time.

## Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for  $dx/dt$ . Such limitations are necessary to satisfy the following constraints:

- When  $x$  is at its saturation limits, the value of  $dx/dt$  must be zero.
- In order for  $x$  to leave the upper limit, the value of  $dx/dt$  must be strictly negative.
- In order for  $x$  to leave its lower limit, the value of  $dx/dt$  must be strictly positive.

Consequently, for such cases, the upper limit of  $dx/dt$  must be strictly positive and the lower limit of  $dx/dt$  must be strictly negative.

When both states are limited, the block determines the states as follows:

- Whenever  $x$  reaches its limits, the resulting behavior is the same as that described in “Limiting  $x$  only”.
- Whenever  $dx/dt$  reaches one of its limits, the resulting behavior is the same as that described in “Limiting  $dx/dt$  only” — including the computation of  $x$  using a first-order

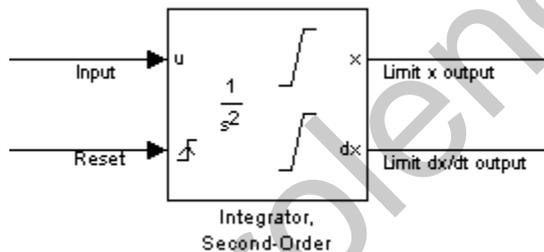

ODE when  $dx/dt$  is held at one of its limits. In such cases, when  $x$  reaches one of its limits, it is held at that limit and  $dx/dt$  is set to zero.

- Whenever both reach their respective limits simultaneously, the state  $x$  behavior overrides  $dx/dt$  behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize  $dx/dt$  at the time when state  $x$  reaches saturation. If the reinitialized value is outside specified limits on  $dx/dt$ , then  $dx/dt$  is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing  $dx/dt$  when  $x$  reaches saturation” on page 1-1550

## Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.

- Select **rising** to reset the states when the reset signal rises from zero to a positive value, from a negative to a positive value, or a negative value to zero.
- Select **falling** to reset the states when the reset signal falls from a positive value to zero, from a positive to a negative value, or from zero to negative.
- Select **either** to reset the states when the reset signal changes from zero to a nonzero value or changes sign.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”).

## Enabling Zero-Crossing Detection

This parameter controls whether zero-crossing detection is enabled for this block. By default, the **Enable zero-crossing detection** parameter is selected on the **Attributes** pane. However, this parameter is only in affect if the **Zero-crossing control**, on the **Solver** pane of the Configuration Parameters dialog, is set to **Use local settings**. For more information, see “Zero-Crossing Detection”.

## Reinitializing $dx/dt$ when $x$ reaches saturation

For certain modeling applications,  $dx/dt$  must be reinitialized when state  $x$  reaches its limits in order to pull  $x$  out of saturation immediately. You can achieve this by selecting **Reinitialize  $dx/dt$  when  $x$  reaches saturation** on the **Attributes** pane.

If this option is on, then at the instant when  $x$  reaches saturation, Simulink checks whether the current value of the  $dx/dt$  initial condition (parameter or signal) allows the state  $x$  to leave saturation immediately. If so, Simulink reinitializes state  $dx/dt$  with the value of the initial condition (parameter or signal) at that instant. If not, Simulink ignores this parameter at the current instant and sets  $dx/dt$  to zero to make the block states consistent.

This parameter only applies at the time when  $x$  actually reaches saturation limit. It does not apply at any future time when  $x$  is being held at saturation.

Refer to the sections on limiting the states for more information. For an example, see the `sldemo_bounce` example.

## Disregarding State Limits and External Reset for Linearization

For cases where you simplify your model by linearizing it, you can have Simulink disregard the limits of the states and the external reset by selecting **Ignore state limits and the reset for linearization**.

## Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the integrator blocks. If this value does not provide sufficient error control, specify a more appropriate value for state  $x$  in the **Absolute tolerance  $x$**  field

and for state  $dx/dt$  in the **Absolute tolerance dx/dt** field of the parameter dialog box. Simulink uses the values that you specify to compute the state values of the block.

## Specifying the Display of the Output Ports

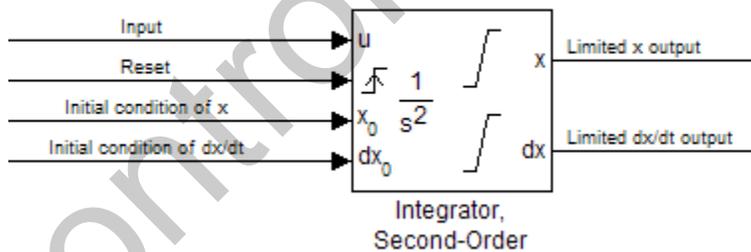

You can control whether or not to display the  $x$  or the  $dx/dt$  output port using the ShowOutput parameter. You can display one output port or both; however, you must select at least one.

## Specifying the State Names

You can specify the name of  $x$  states and  $dx/dt$  states using the StateNameX and StateNameDXDT parameters. However, you must specify names for either both or neither; you cannot specify names for just  $x$  or just  $dx/dt$ . Both state names must have identical type and length. Furthermore, the number of names must evenly divide the number of states.

## Selecting All Options

When you select all options, the block icon looks like this.

## Data Type Support

The Integrator block accepts and outputs signals of type **double** on its data ports. The external reset port accepts signals of type **double** or **Boolean**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

## Initial condition source x

Specify the initial condition source for state  $x$ .

### Settings

**Default:** internal

internal

Get the initial conditions of state  $x$  from the **Initial condition x** parameter.

external

Get the initial conditions of state  $x$  from an external block.

### Tip

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

### Dependencies

Selecting `internal` enables the **Initial condition x** parameter.

Selecting `external` disables the **Initial condition x** parameter..

### Command-Line Information

**Parameter:** ICSourceX

**Type:** character vector

**Value:** 'internal' | 'external'

**Default:** 'internal'

## Initial condition x

Specify the initial condition of state  $x$ .

### Settings

**Default:** 0.0

### Tip

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

### Dependencies

Setting **Initial condition source x** to `internal` enables this parameter.

Setting **Initial condition source x** to `external` disables this parameter.

### Command-Line Information

**Parameter:** ICX

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

## Limit x

Limit state  $x$  of the block to a value between the **Lower limit x** and **Upper limit x** parameters.

### Settings

**Default:** Off for Second-Order Integrator, On for Second-Order Integrator Limited

On

Limit state  $x$  to a value between the **Lower limit x** and **Upper limit x** parameters.

Off

Do not limit the state  $x$  output to a value between the **Lower limit x** and **Upper limit x** parameters.

### Dependencies

This parameter enables **Upper limit x** parameter.

This parameter enables **Lower limit x** parameter.

### Command-Line Information

**Parameter:** LimitX

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Upper limit $x$

Specify the upper limit of state  $x$ .

### Settings

**Default:** `inf` for Second-Order Integrator, 1 for Second-Order Integrator Limited

### Tip

The upper saturation limit for state  $x$  must be strictly greater than the lower saturation limit.

### Dependency

**Limit  $x$**  enables this parameter.

### Command-Line Information

**Parameter:** `UpperLimitX`

**Type:** scalar or vector

**Value:** `'inf'`

**Default:** `'inf'`

Controlengineers.ir

## Lower limit $x$

Specify the lower limit of state  $x$ .

### Settings

**Default:**  $-\infty$  for Second-Order Integrator, 0 for Second-Order Integrator Limited

### Tip

The lower saturation limit for state  $x$  must be strictly less than the upper saturation limit.

### Dependencies

**Limit  $x$**  enables this parameter.

### Command-Line Information

**Parameter:** LowerLimitX

**Type:** scalar or vector

**Value:**  $-\infty$

**Default:**  $-\infty$

Controlengineers.ir

## Wrap x

Enable wrapping of  $x$  between the **Wrapped upper value x** and **Wrapped lower value x** parameters. Enabling wrapping of  $x$  eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

### Settings

**Default:** off

On

Enable wrapping of  $x$  between the **Wrapped upper value x** and **Wrapped lower value x** parameters.

If you specify **Wrapped upper value x** as `inf` and **Wrapped lower value x** as `-inf`, wrapping will never occur.

Off

Do not enable wrapping of  $x$ .

### Dependencies

This parameter enables **Wrapped upper value x**.

This parameter enables **Wrapped lower value x**.

### Command-Line Information

**Parameter:** WrapX

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Wrapped upper value $x$

Specify the upper value for wrapping  $x$ .

### Settings

Default: 'pi'

### Dependencies

Wrap  $x$  enables this parameter.

### Command-Line Information

Parameter: WrappedUpperValueX

Type: scalar or vector

Value: '2\*pi'

Default: 'pi'

Controlengineers.ir

## Wrapped lower value $x$

Specify the lower value for wrapping  $x$ .

### Settings

Default:  $-\pi$

### Dependencies

Wrap  $x$  enables this parameter.

### Command-Line Information

Parameter: WrappedLowerValueX

Type: scalar or vector

Value: '0'

Default: '-pi'

Controlengineers.ir

## Absolute tolerance $x$

Specify the absolute tolerance for computing state  $x$ .

### Settings

**Default:** auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute state  $x$ .
- If you enter a real scalar value, that value overrides the absolute tolerance in the Configuration Parameters dialog box and is used for computing all  $x$  states.
- If you enter a real vector, the dimension of that vector must match the dimension of state  $x$ . These values override the absolute tolerance in the Configuration Parameters dialog box.

### Command-Line Information

**Parameter:** AbsoluteToleranceX

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

## State name $x$

Assign a unique name to state  $x$ .

### Settings

**Default:** ''

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple  $x$  states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for  $x$ , you must also specify a state name for  $dx/dt$ .
- State names for  $x$  and  $dx/dt$  must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than  $x$  states, but you cannot specify more names than  $x$  states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for  $dx/dt$ .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector or a cell array.

### Command-Line Information

**Parameter:** StateNameX

**Type:** character vector

**Value:** '' | user-defined

**Default:** ''

## Initial condition source $dx/dt$

Specify the initial condition source for state  $dx/dt$ .

### Settings

**Default:** internal

internal

Get the initial conditions of state  $dx/dt$  from the **Initial condition  $dx/dt$**  parameter.

external

Get the initial conditions of state  $dx/dt$  from an external block.

### Tip

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

### Dependencies

Selecting `internal` enables the **Initial condition  $dx/dt$**  parameter.

Selecting `external` disables the **Initial condition  $dx/dt$**  parameter.

### Command-Line Information

**Parameter:** ICSourceDXDT

**Type:** character vector

**Value:** 'internal' | 'external'

**Default:** 'internal'

## Initial condition $dx/dt$

Specify the initial condition of state  $dx/dt$ .

### Settings

**Default:** 0.0

### Tip

Simulink software does not allow the initial condition of this block to be  $\text{inf}$  or  $\text{NaN}$ .

### Dependencies

Setting **Initial condition source  $dx/dt$**  to **internal** enables this parameter.

Setting **Initial condition source  $dx/dt$**  to **external** disables this parameter.

### Command-Line Information

**Parameter:** ICDXDT

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

## Limit $dx/dt$

Limit the  $dx/dt$  state of the block to a value between the **Lower limit  $dx/dt$**  and **Upper limit  $dx/dt$**  parameters.

### Settings

**Default:** Off for Second-Order Integrator, On for Second-Order Integrator Limited

On

Limit state  $dx/dt$  of the block to a value between the **Lower limit  $dx/dt$**  and **Upper limit  $dx/dt$**  parameters.

Off

Do not limit state  $dx/dt$  of the block to a value between the **Lower limit  $dx/dt$**  and **Upper limit  $dx/dt$**  parameters.

### Tip

If you set saturation limits for  $x$ , then the interval defined by the **Upper limit  $dx/dt$**  and **Lower limit  $dx/dt$**  must contain zero.

### Dependencies

This parameter enables **Upper limit  $dx/dt$** .

This parameter enables **Lower limit  $dx/dt$** .

### Command-Line Information

**Parameter:** LimitDXDT

**Type:** character vector

**Value:** 'Off' | 'On'

**Default:** 'Off'

## Upper limit $dx/dt$

Specify the upper limit for state  $dx/dt$ .

### Settings

**Default:** 'inf'

### Tip

If you limit  $x$ , then this parameter must have a strictly positive value.

### Dependencies

**Limit  $dx/dt$**  enables this parameter.

### Command-Line Information

**Parameter:** UpperLimitDXDT

**Type:** scalar or vector

**Value:** 'inf'

**Default:** 'inf'

Controlengineers.ir

## Lower limit $dx/dt$

Specify the lower limit for state  $dx/dt$ .

### Settings

Default: '-inf'

### Tip

If you limit  $x$ , then this parameter must have a strictly negative value.

### Dependencies

Limit  $dx/dt$  enables this parameter.

### Command-Line Information

Parameter: LowerLimitDXDT

Type: scalar or vector

Value: '-inf'

Default: '-inf'

Controlengineers.ir

## Absolute tolerance $dx/dt$

Specify the absolute tolerance for computing state  $dx/dt$ .

### Settings

**Default:** auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the  $dx/dt$  output of the block.
- If you enter a numeric value, that value overrides the absolute tolerance in the Configuration Parameters dialog box.

### Command-Line Information

**Parameter:** AbsoluteToleranceDXDT

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

## State name $dx/dt$

Assign a unique name to state  $dx/dt$ .

### Settings

**Default:** ''

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple  $dx/dt$  states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for  $dx/dt$ , you must also specify a state name for  $x$ .
- State names for  $x$  and  $dx/dt$  must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than  $dx/dt$  states, but you cannot specify more names than  $dx/dt$  states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for  $x$ .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector or a cell array.

### Command-Line Information

**Parameter:** StateNameDXDT

**Type:** character vector

**Value:** '' | user-defined

**Default:** ''

## External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

### Settings

**Default:** none

none

Do not reset the state to initial conditions.

rising

Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.

falling

Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.

either

Reset the state when the reset signal changes from zero to a nonzero value or changes sign.

### Command-Line Information

**Parameter:** ExternalReset

**Type:** character vector

**Value:** 'none' | 'rising' | 'falling' | 'either'

**Default:** 'none'

## Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

**Default:** On

On  
Enable zero-crossing detection.

Off  
Do not enable zero-crossing detection.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Reinitialize $dx/dt$ when $x$ reaches saturation

At the instant when state  $x$  reaches saturation, reset  $dx/dt$  to its current initial conditions.

### Settings

**Default:** Off

On

Reset  $dx/dt$  to its initial conditions when  $x$  becomes saturated.

Off

Do not reset  $dx/dt$  to its initial conditions when  $x$  becomes saturated.

### Tip

The  $dx/dt$  initial condition must have a value that enables  $x$  to leave saturation immediately. Otherwise, Simulink ignores the initial conditions for  $dx/dt$  to preserve mathematical consistency of block states.

### Command-Line Information

**Parameter:** ReinitDXDTwhenXreachesSaturation

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Ignore state limits and the reset for linearization

For linearization purposes, have Simulink ignore the specified state limits and the external reset.

### Settings

**Default:** Off

On

Ignore the specified state limits and the external reset.

Off

Apply the specified state limits and the external reset setting.

### Command-Line Information

**Parameter:** IgnoreStateLimitsAndResetForLinearization

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Show output

Specify the output ports on the block.

### Settings

**Default:** both

both

Show both  $x$  and  $dx/dt$  output ports.

$x$

Show only the  $x$  output port.

$dx/dt$

Show only the  $dx/dt$  output port.

### Command-Line Information

**Parameter:** ShowOutput

**Type:** character vector

**Value:** 'both' | 'x' | 'dxdt'

**Default:** 'both'

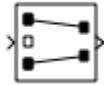

### Characteristics

Data Types	Double
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

**Introduced in R2010a**

# Selector

Select input elements from vector, matrix, or multidimensional signal

## Library

Signal Routing

## Description

The Selector block generates as output selected or reordered elements of an input vector, matrix, or multidimensional signal.

A Selector block accepts vector, matrix, or multidimensional signals as input. The parameter dialog box and the block's appearance change to reflect the number of dimensions of the input.

Based on the value you enter for the **Number of input dimensions** parameter, a table of indexing settings is displayed. Each row of the table corresponds to one of the input dimensions in **Number of input dimensions**. For each dimension, you define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. When you configure the Selector block for multidimensional signal operations, the block icon changes.

For example, assume a 6-D signal with a one-based index mode. The table of the Selector block dialog changes to include one row for each dimension. Suppose that you define each dimension with the following entries:

- Dimension 1
  - **Index Option**, select `Select all`

- Dimension 2
  - **Index Option**, select Starting index (dialog)
  - **Index**, enter 2
  - **Output Size**, enter 5
- Dimension 3
  - **Index Option**, select Index vector (dialog)
  - **Index**, enter [1 3 5]
- Dimension 4
  - **Index Option**, select Starting index (port)
  - **Output Size**, enter 8
- Dimension 5
  - **Index Option**, select Index vector (port)
- Dimension 6
  - **Index Option**, select Starting and ending indices (port)

The output will be  $Y=U(1:end, 2:6, [1\ 3\ 5], \text{Idx4:Idx4+7}, \text{Idx5}, \text{Idx6}(1):\text{Idx6}(2))$ , where  $\text{Idx4}$ ,  $\text{Idx5}$ , and  $\text{Idx6}$  are the index ports for dimensions 4, 5, and 6.

You can use an array of buses as an input signal to a Selector block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Data Type Support

The data port of the Selector block accepts signals of any signal type and any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. The data port accepts mixed-type signals. The index port accepts built-in data types, but not Boolean. The elements of the output have the same type as the corresponding selected input elements.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

---

**Note:** The Selector block is not designed to accept virtual bus input signals. For virtual bus inputs, use a Bus Selector block instead of a Selector block.

---

## Parameters

### Number of input dimensions

Enter the number of dimensions of the input signal.

### Index mode

Specifies the indexing mode: **One-based** or **Zero-based**. If **One-based** is selected, an index of 1 specifies the first element of the input vector, 2, the second element, and so on. If **Zero-based** is selected, an index of 0 specifies the first element of the input vector, 1, the second element, and so on.

### Index Option

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

- Select all

No further configuration is required. All elements are selected.

- Index vector (dialog)

Enables the **Index** column. Enter the vector of indices of the elements.

- Index vector (port)

No further configuration is required.

- Starting index (dialog)

Enables the **Index** and **Output Size** columns. Enter the starting index of the range of elements to select in the **Index** column and the number of elements to select in the **Output Size** column.

- Starting index (port)

Enables the **Output Size** column. Enter the number of elements to be selected in the **Output Size** column.

- Starting and ending indices (port)

No further configuration is required.

Using this option results in a variable-size output signal. When you update, the output dimension is set to be the same as the input signal dimension. During execution, the output dimension is updated based on the signal feeding the index.

When logging output signal data, signals not selected are padded with NaN values.

The **Index** and **Output Size** columns appear as needed.

### Index

If the **Index Option** is **Index vector** (dialog), enter the index of each element in which you are interested.

If the **Index Option** is **Starting index vector** (dialog), enter the starting index of the range of elements to be selected.

### Output Size

Enter the width (number of elements from the starting point) of the block output signal.

### Input port size

Specify the width of the block input signal (-1 for inherited) — 1-D signals only.

### Sample time

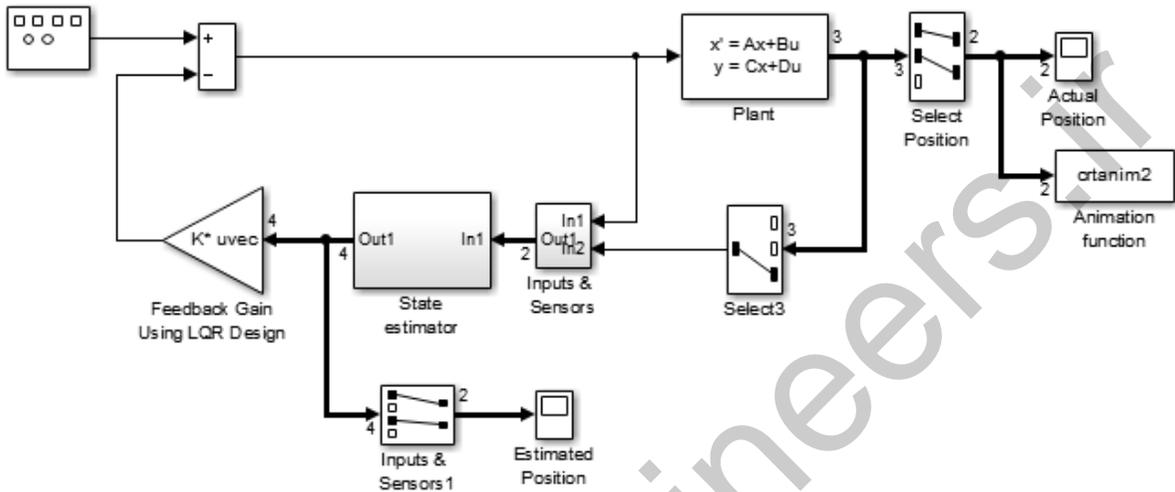

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

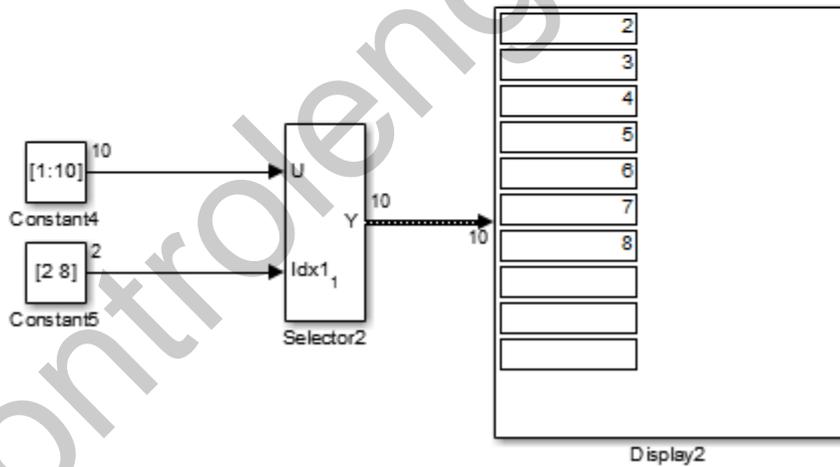

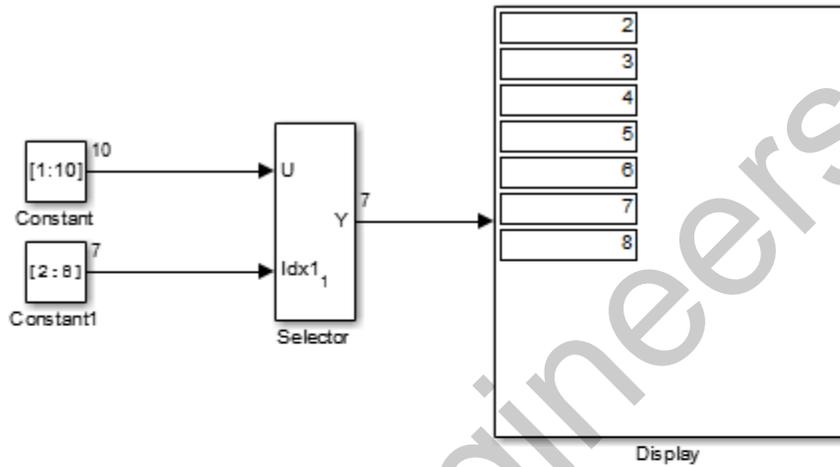

The `sldemo_dblcart1` model shows the use of three Selector blocks. The following diagram shows what the model looks like after you enable **Display > Signals & Ports > Signal Dimensions** and simulate the model.

All three Selector blocks set the **Index Option** to **Index vector** (dialog), which allows you to specify the indices of the specific signals that you want to select, using the **Index** parameter. The **Input port size** parameter is set to the dimension of the largest input signal.

The following model shows the result of simulating two Selector blocks that have the same kind of input signals, but which have two different **Index Option** settings.

Both Selector blocks select 7 values from the input signal that feeds the U port. However, the Selector block outputs a fixed-size signal, whereas the Selector2 block outputs a variable-size signal whose compiled signal dimension is 10 instead of 7.

The **Selector** block sets **Index Option** to Index vector (port), which uses the input signal from **Constant1** as the index vector. The dimension of the input signal is 7, so the **Display** block shows the 7 values of the **Constant1** block. The **Selector2** block

sets the **Input port size** parameter to 10, which is the size of the largest input signal to the Selector1 block.

The Selector2 block uses the same configuration as the Selector block, except that the **Index Option** is set to Starting and ending indices (port). The output uses the size of **Input port size** parameter (10), even though the size of the input signal is 7. The Display2 block shows empty boxes for the three extra dimensions.

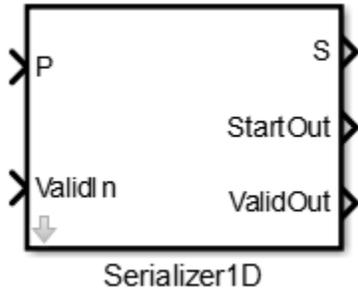

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

## Serializer1D

Convert vector signal to scalar or smaller vectors

## Library

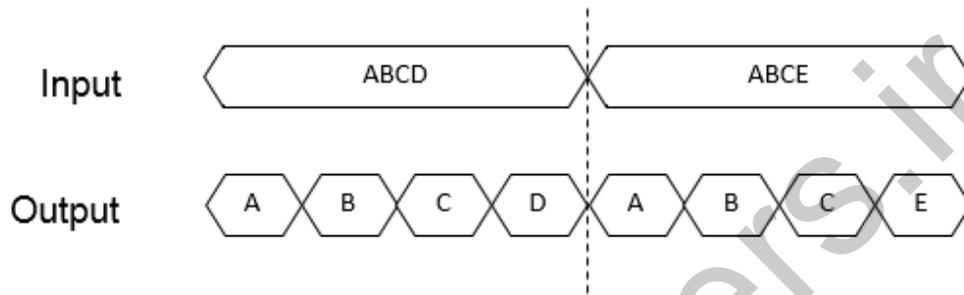

HDL Coder / HDL Operations

## Description

The Serializer1D block converts a slower vector signal into a faster stream of scalar signals or smaller size vector signals based on the **Ratio** and **Idle Cycle** values. To match the faster serialized output, the sample time changes according to this equation:

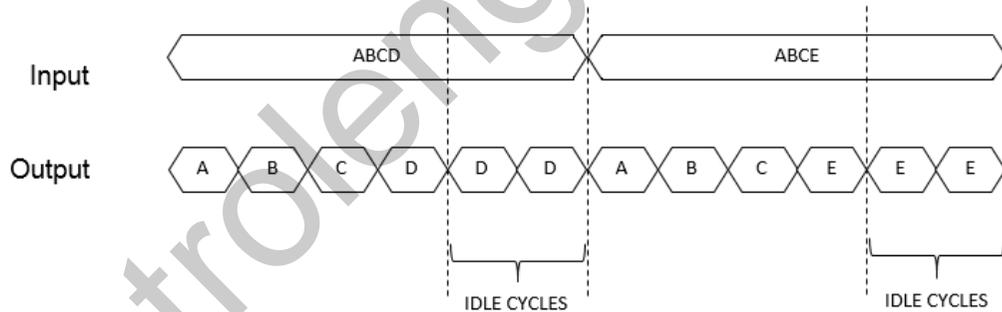

$$\text{Output Sample Time} = \text{Input Sample Time} / (\text{Ratio} + \text{Idle Cycles})$$

Consider this example where the input data is a vector of size 4 and the **Ratio** is set to 4.

The output data serializes each of the vector signals into four scalar signals. The sample time at the output is:  $Output\ Sample\ Time = Input\ Sample\ Time / 4$ .

To add idle cycles at the end of each output, for **Idle Cycles**, specify an integer greater than zero. Consider this example with **Ratio** set to 4 and **Idle Cycles** set to 2.

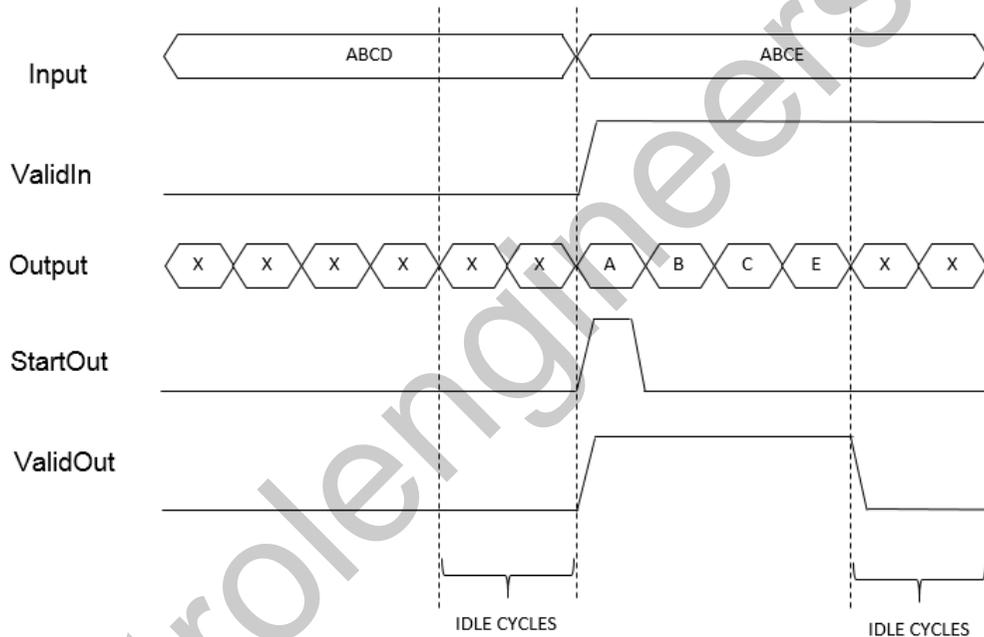

For each slow vector signal, the output has six fast cycles consisting of the four serialized scalar signals and two idle cycles. The sample time at the output is  $Output\ Sample\ Time = Input\ Sample\ Time / 6$ .

The Serializer1D block provides three control signals: **ValidIn**, **ValidOut**, and **StartOut**. You can use **ValidIn** to control **ValidOut** and **StartOut**. The serialized output does not depend on **ValidIn**. To determine whether the output serialized data is valid, use **ValidIn** and **ValidOut**. If you give a high input to **ValidIn**, and if there are no

idle cycles, **ValidOut** gives a high output, which indicates that the output serialized data is valid.

Consider an example that has input data as a vector of size 4, **Ratio** set to 4, **Idle Cycles** set to 2, and uses all three control signals.

For the first input vector, **ABCD**, **ValidIn** is false. **StartOut** and **ValidOut** become false. This means that the output data values are not valid. In the waveform, the data values are represented as **X**, which correspond to *don't care* values.

For the second input vector, **ABCE**, **ValidIn** is true. The output data serializes the vector into four scalar signals. The control signal **StartOut** becomes true at output **A** to indicate the start of deserialization. In the next cycle, the **StartOut** signal becomes false. **ValidOut** is true for all four output signals indicating valid output data for the four cycles. **ValidOut** becomes false for the idle cycles, and the output data values are *don't care* values.

## HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

## Parameters

### Ratio

Serialization factor, specified as a positive scalar. Default is 1.

The ratio is equal to the size of the input vector divided by the size of the output vector. Input vector size must be divisible by the ratio.

### Idle Cycles

Number of idle cycles to add at the end of each output. Default is 0.

### ValidIn

Activates the **ValidIn** port. Default is **off**.

### StartOut

Activates the **StartOut** port. Default is **off**.

### ValidOut

Activates the **ValidOut** port. Default is **off**.

### Input data port dimensions (-1 for inherited)

Size of the input data signal. Input vector size must be divisible by the ratio. By default, the block inherits size based on the context within the model.

### Input sample time (-1 for inherited)

Time interval between sample time hits, or another appropriate sample time such as continuous. By default, the block inherits sample time based on context within the model. For more information, see “Sample Time”.

### Input signal type

Input signal type of the block, specified as **auto**, **real**, or **complex**. Default is **auto**.

## Ports

P

Input signal to serialize. Bus data types are not supported.

ValidIn

Input control signal. This port is available when you select the **ValidIn** check box.

Data type: Boolean

S

Serialized output signal. Bus data types are not supported.

StartOut

Output control signal that indicates where to start deserialization. You can use this signal as the **StartIn** input to the **Deserializer1D** block. To use this port, select the **StartOut** check box.

Data type: Boolean

ValidOut

Output control signal that indicates valid output signal. You can use this signal as the **ValidIn** input to the **Deserializer1D** block. This port is available when you select the **ValidOut** check box.

Data type: Boolean

## S-Function

Include S-function in model

## Library

User-Defined Functions

## Description

The S-Function block provides access to S-functions from a block diagram. The S-function named as the **S-function name** parameter can be a Level-1 MATLAB or a Level-1 or Level-2 C MEX S-function (see “S-Function Basics” for information on how to create S-functions).

---

**Note:** Use the Level-2 MATLAB S-Function block to include a Level-2 MATLAB S-function in a block diagram.

---

The S-Function block allows additional parameters to be passed directly to the named S-function. The function parameters can be specified as MATLAB expressions or as variables separated by commas. For example,

A, B, C, D, [eye(2,2);zeros(2,2)]

Note that although individual parameters can be enclosed in brackets, the list of parameters must not be enclosed in brackets.

The S-Function block displays the name of the specified S-function and the number of input and output ports specified by the S-function. Signals connected to the inputs must have the dimensions specified by the S-function for the inputs.

## Data Type Support

Depends on the implementation of the S-Function block.

## Parameters

### S-function name

The S-function name.

### S-function parameters

Additional S-function parameters. See the preceding block description for information on how to specify the parameters.

### S-function modules

This parameter applies only if this block represents a C MEX S-function and you intend to use the Simulink Coder software to generate code from the model containing the block. If you use it, when you are ready to generate code, you must force the coder to rebuild the top model as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

For more information on using this parameter, see “Specify Additional Source Files for an S-Function” (Simulink Coder) in the Simulink Coder documentation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Depends on contents of S-function
Direct Feedthrough	Depends on contents of S-function
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

# S-Function Builder

Create S-function from C code that you provide

## Library

User-Defined Functions

## Description

The S-Function Builder block creates a C MEX S-function from specifications and C source code that you provide. See “Build S-Functions Automatically” for detailed instructions on using the S-Function Builder block to generate an S-function.

Instances of the S-Function Builder block also serve as wrappers for generated S-functions in Simulink models. When simulating a model containing instances of an S-Function Builder block, Simulink software invokes the generated S-function associated with each instance to compute the instance's output at each time step.

---

**Note:** The S-Function Builder block does not support masking. However, you can mask a Subsystem block that contains an S-Function Builder block. For more information, see “Dynamic Masked Subsystem”.

---

## Data Type Support

The S-Function Builder can accept and output complex, 1-D, or 2-D signals and nonvirtual buses. For each of these cases, the signals must have a data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

See “S-Function Builder Dialog Box” in the online documentation for information on using the S-Function Builder block's parameter dialog box.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

## Shift Arithmetic

Shift bits or binary point of signal

$$\begin{cases} Q_y = Q_u \gg 8 \\ V_y = V_u * 2^{-8} \\ E_y = E_u \end{cases}$$

## Library

Logic and Bit Operations

## Description

### Supported Shift Operations

The Shift Arithmetic block can shift the bits or the binary point of an input signal, or both.

For example, shifting the binary point on an input of data type `sfixed(8)`, by two places to the right and left, gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Binary point shift right by two places	1100101.1	-26.5
Binary point shift left by two places	110.01011	-1.65625

This block performs arithmetic bit shifts on signed numbers. Therefore, the block recycles the most significant bit for each bit shift. Shifting the bits on an input of data type `sfixed(8)`, by two places to the right and left, gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Bit shift right by two places	11110.010	-1.75
Bit shift left by two places	00101.100	5.5

## Data Type Support

The block supports input signals of the following data types:

Input Signal	Supported Data Types
u	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed point</li> </ul>
s	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed-point integer</li> </ul>

The following rules determine the output data type:

Data Type of Input u	Output Data Type
Floating point	Same as input u
Built-in integer or fixed point	<ul style="list-style-type: none"> <li>Sign of u</li> <li>Word length of u</li> <li>Slope of <math>u * 2^{(\max(\text{binary points to shift}))}</math></li> <li>Bias of <math>u * 2^{(\max(\text{binary points to shift} - \text{bits to shift}))}</math>, for bit shifts where the direction is bidirectional or right</li> <li>Bias of <math>u * 2^{(\max(\text{binary points to shift} + \text{bits to shift}))}</math>, for bit shifts where the direction is left</li> </ul>

The block parameters support the following data types:

Parameter	Supported Data Types
<b>Bits to shift: Number</b>	<ul style="list-style-type: none"> <li>Built-in integer</li> <li>Fixed-point integer</li> </ul>
<b>Binary points to shift</b>	<ul style="list-style-type: none"> <li>Built-in integer</li> <li>Fixed-point integer</li> </ul>

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Bits to shift: Source

Specify whether to enter the bits to shift on the dialog box or to inherit the values from an input port.

### Bits to shift: Direction

Specify the direction in which to shift bits: left, right, or bidirectional.

### Bits to shift: Number

Specify a scalar, vector, or array of bit shift values. This parameter is available when **Bits to shift: Source** is Dialog.

If the direction is...	Then...
Left or Right	Use positive integers to specify bit shifts.
Bidirectional	Use positive integers for right shifts and negative integers for left shifts.

### Binary points to shift

Specify an integer number of places to shift the binary point of the input signal. A positive value indicates a right shift, while a negative value indicates a left shift.

### Diagnostic for out-of-range shift value

Specify whether to produce a warning or error during simulation when the block contains an out-of-range shift value. Options include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error

For more information, see “Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values” on page 1-1595.

### Check for out-of-range 'Bits to shift' in generated code

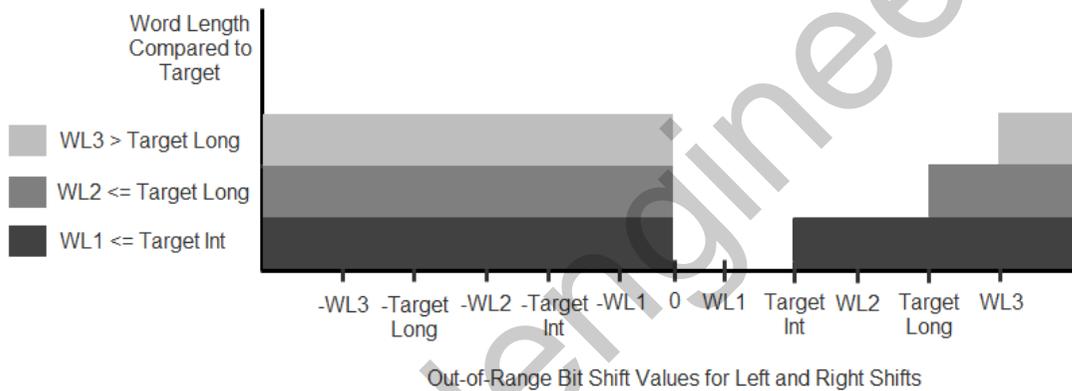

Select this check box to include conditional statements in the generated code that protect against out-of-range bit shift values. This check box is available when **Bits to shift: Source** is Input port.

For more information, see “Code Generation for Out-of-Range Bit Shift Values” on page 1-1596.

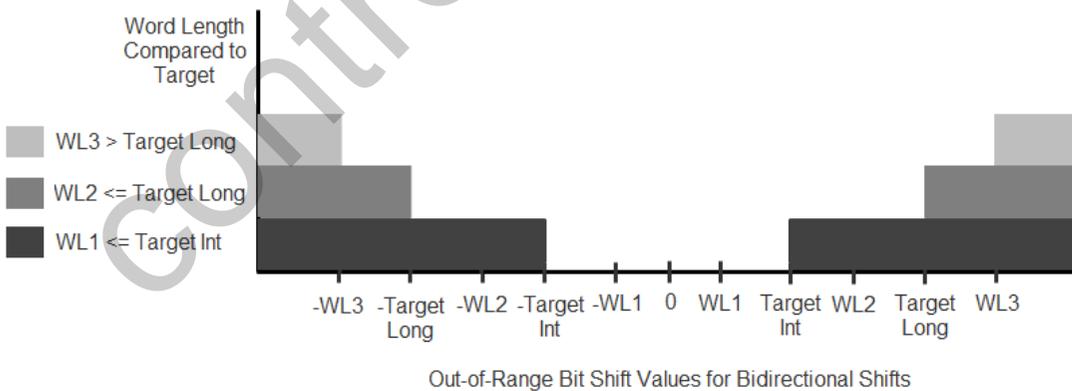

## Out-of-Range Bit Shifts

### Definition of an Out-of-Range Bit Shift

Suppose that WL is the input word length. The shaded regions in the following diagram show out-of-range bit shift values for left and right shifts.

Similarly, the shaded regions in the following diagram show out-of-range bit shift values for bidirectional shifts.

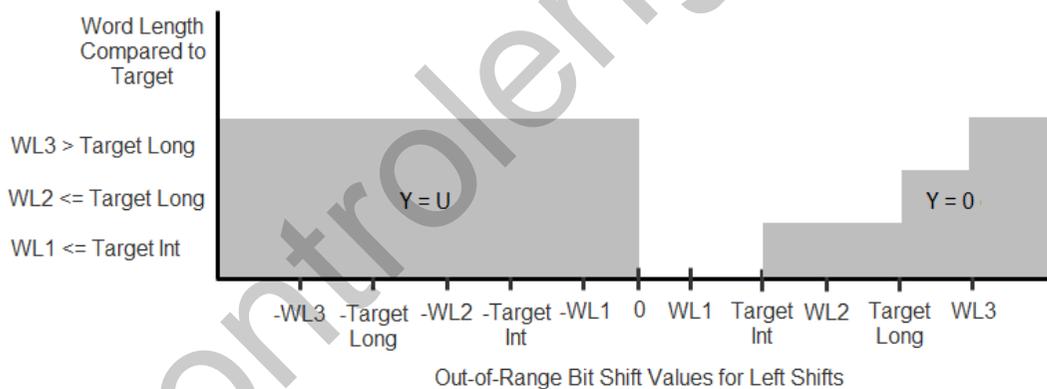

The diagnostic for out-of-range bit shifts responds as follows, depending on the mode of operation:

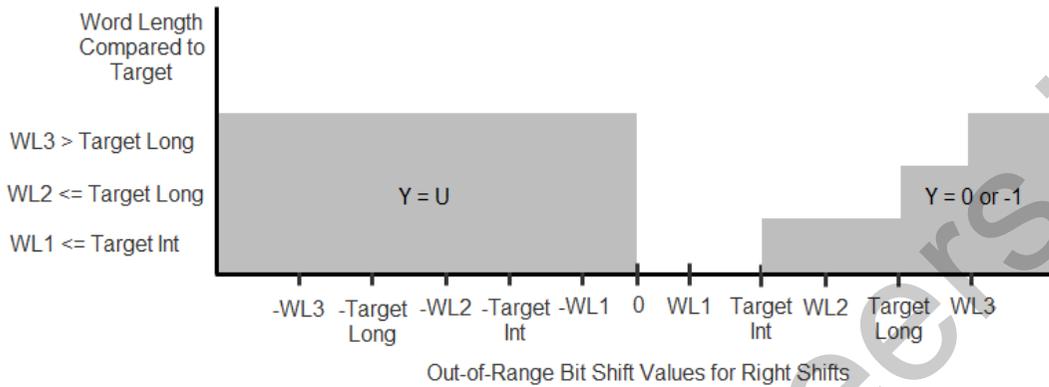

Mode	Diagnostic for out-of-range shift value		
	None	Warning	Error
Simulation	Do not report any warning or error.	Report a warning but continue simulation.	Report an error and stop simulation.
Accelerator modes and code generation	Has no effect.		

### Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values

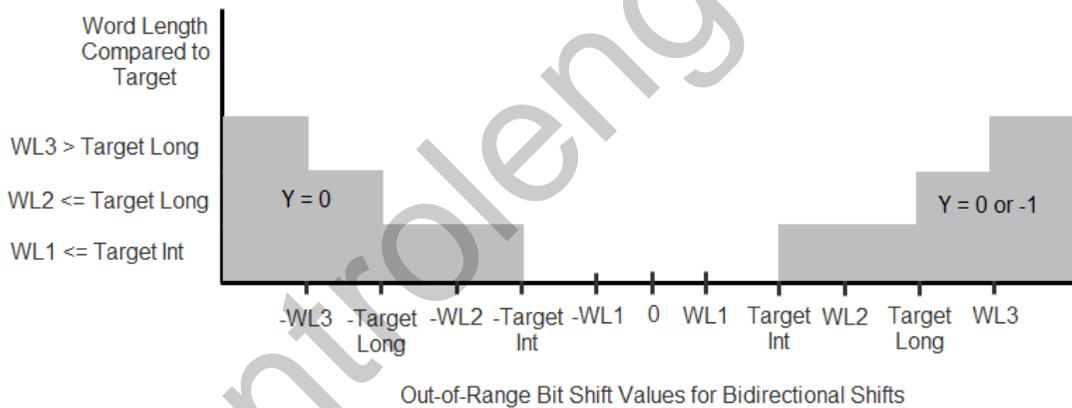

Suppose that  $U$  is the input,  $WL$  is the input word length, and  $Y$  is the output. The output for an out-of-range bit shift value for left shifts is as follows:

Similarly, the output for an out-of-range bit shift value for right shifts is as follows:

For bidirectional shifts, the output for an out-of-range bit shift value is as follows:

## Code Generation for Out-of-Range Bit Shift Values

For the generated code, the method for handling out-of-range bit shifts depends on the setting of **Check for out-of-range 'Bits to shift' in generated code**.

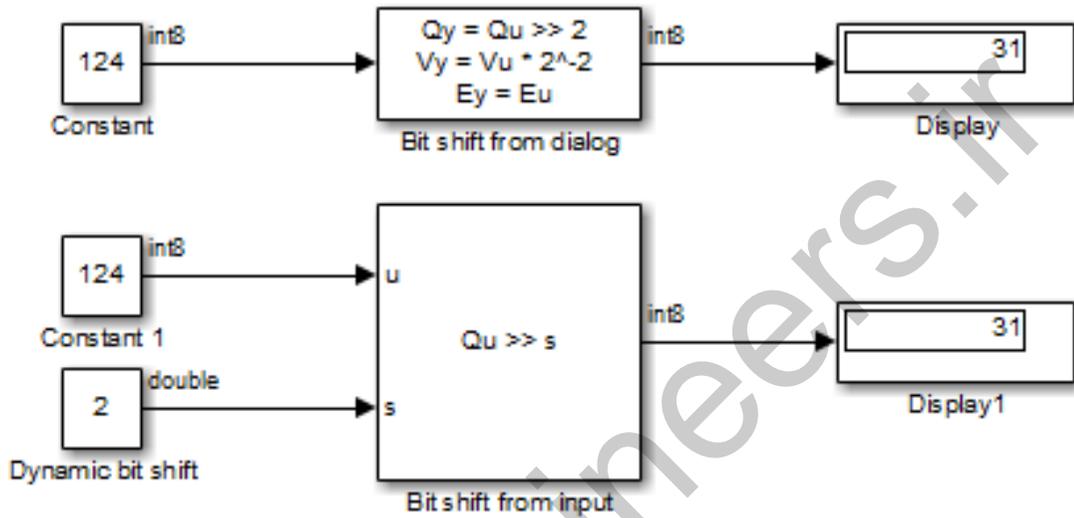

Check Box Setting	Generated Code	Simulation Results Compared to Generated Code
Selected	Includes conditional statements to protect against out-of-range bit shift values.	Simulation and Accelerator mode results match those of code generation.
Cleared	Does not protect against out-of-range bit shift values.	<ul style="list-style-type: none"> <li>For in-range values, simulation and Accelerator mode results match those of code generation.</li> <li>For out-of-range values, the code generation results are compiler specific.</li> </ul>

For right shifts on signed negative inputs, most C compilers use an arithmetic shift instead of a logical shift. Generated code for the Shift Arithmetic block depends on this compiler behavior.

## Examples

### Block Output for Right Bit Shifts

The following model compares the behavior of right bit shifts using the dialog box versus the block input port.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8
Dynamic bit shift	Constant value	2
	Output data type	Inherit: Inherit from 'Constant value'

The key block parameter settings of the Shift Arithmetic blocks are:

Block	Parameter	Setting
Bit shift from dialog	Bits to shift: Source	Dialog
	Bits to shift: Direction	Right
	Bits to shift: Number	2
Bit shift from input	Bits to shift: Source	Input port
	Bits to shift: Direction	Right

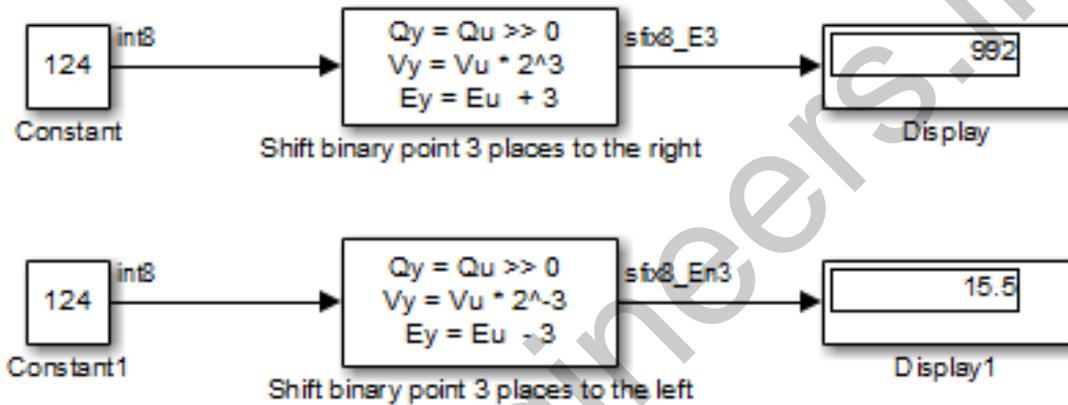

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the number of bits two places to the right produces 00011111 in binary format. Therefore, the block outputs 31.

The bottom Shift Arithmetic block performs the same operation as the top block. However, the bottom block receives the bit shift value through an input port instead of the dialog box. By supplying this value as an input signal, you can change the number of bits to shift during simulation.

Controlengineers.ir

## Block Output for Binary Point Shifts

The following model shows the effect of binary point shifts.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8

The key block parameter settings of the Shift Arithmetic blocks are:

Block	Parameter	Setting
Shift binary point 3 places to the right	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0
	Binary points to shift: Number	3
Shift binary point 3 places to the left	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0

Block	Parameter	Setting
	Binary points to shift: Number	-3

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the binary point three places to the right produces 01111100000 in binary format. Therefore, the top block outputs 995.

The bottom Shift Arithmetic block also takes an input of 124. Shifting the binary point three places to the left produces 01111.100 in binary format. Therefore, the bottom block outputs 15.5.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

# Sign

Indicate sign of input

## Library

Math Operations

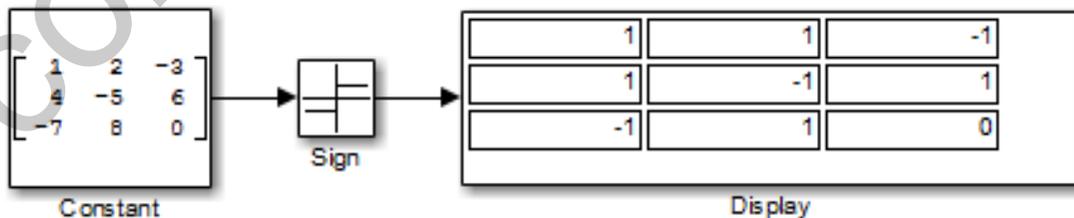

## Description

### Block Behavior for Real Inputs

For real inputs, the Sign block outputs the sign of the input:

Input	Output
Greater than zero	1
Equal to zero	0
Less than zero	-1

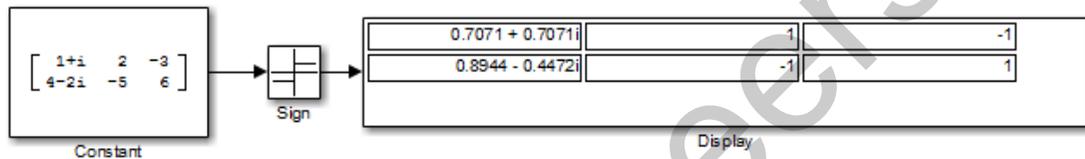

For vector and matrix inputs, the block outputs a vector or matrix where each element is the sign of the corresponding input element, as shown in this example:

## Block Behavior for Complex Inputs

When the input  $u$  is a complex scalar, the block output matches the MATLAB result for:  $\text{sign}(u) = u ./ \text{abs}(u)$

When an element of a vector or matrix input is complex, the block uses the same formula that applies to scalar input, as shown in this example:

## Data Type Support

The Sign block supports real inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The block supports complex inputs only for floating-point data types, **double** and **single**. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Examples

The following Simulink examples show how to use the Sign block:

- sldemo\_fuelsys (in the Engine Gas Dynamics/Throttle & Manifold/Throttle subsystem)
- sldemo\_hardstop

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

**Introduced before R2006a**

# Signal Builder

Create and generate interchangeable groups of signals whose waveforms are piecewise linear

## Library

Sources

## Description

The Signal Builder block allows you to create interchangeable groups of piecewise linear signal sources and use them in a model. See “Signal Groups”.

---

**Note:** Use the `signalbuilder` function to create and access Signal Builder blocks programmatically.

---

## Data Type Support

The Signal Builder block accepts signals only of type `double` and outputs a virtual nonhierarchical bus, scalar, or array of real signals of type `double`. It does not support data stores (see “Data Stores”).

For more information, see “Data Types Supported by Simulink”.

## Parameters

The Signal Builder block has the same dialog box as that of a Subsystem block. To display the dialog box, right-click the block and select **Subsystem Parameters**.

## Examples

The following examples show how to use the Signal Builder block:

- sldemo\_pid2dof
- sf\_test\_vectors

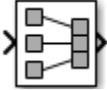

## Characteristics

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter, accessible by selecting <b>File &gt; Simulation Options</b> in the Signal Builder block <ul style="list-style-type: none"> <li>• Zero represents a continuous sample time.</li> <li>• A positive integer represents a discrete sample time.</li> </ul>
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

Introduced before R2006a

# Signal Conversion

Convert signal to new type without altering signal values

## Library

Signal Attributes

## Description

The Signal Conversion block converts a signal from one type to another. Use the **Output** parameter to select the type of conversion to perform.

## Data Type Support

The Signal Conversion block accepts signals of the following data types:

- Scalar
- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Virtual and nonvirtual bus signals

You can use an array of buses as an input signal to a Signal Conversion block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

For more information about data types, see “Data Types Supported by Simulink”.

## Parameters

### Output

Specify the type of conversion to perform. The type of conversion that you use depends on your modeling goal.

Modeling Goal	Output Option
Reduce generated code for a muxed signal.  For an example involving Simulink Coder software, see “Reusable Code and Referenced Models” (Simulink Coder).	Signal copy
Connect a block with a constant sample time to an output port of an enabled subsystem.	Signal copy
Pass a bus signal, or array of buses signal, whose components have different data types to a nonvirtual Inport block in an atomic subsystem that has direct feedthrough.  For more information, see “Composite Signals”.	Signal copy
Save memory by converting a nonvirtual bus to a virtual bus.	Virtual bus
Pass a virtual bus signal to a modeling construct that requires a nonvirtual bus, such as a Model block.	Nonvirtual bus
Pass a nonvirtual bus signal from a Bus Selector block.	Nonvirtual bus

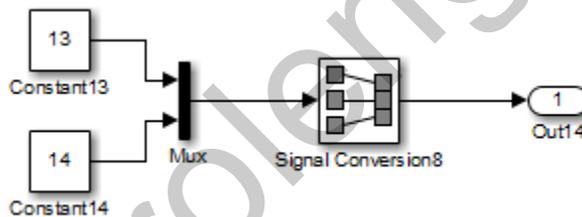

- The **Signal copy** option is the default. The type of conversion that the Signal Conversion block performs using the **Signal copy** option depends on the type of input signal.

Type of Input Signal	Conversion that the Signal Copy Option Performs
Muxed (nonbus) signal	Converts the muxed signal, whose elements occupy discontinuous areas of memory, to a vector signal, whose elements occupy contiguous areas of memory. The conversion allocates a

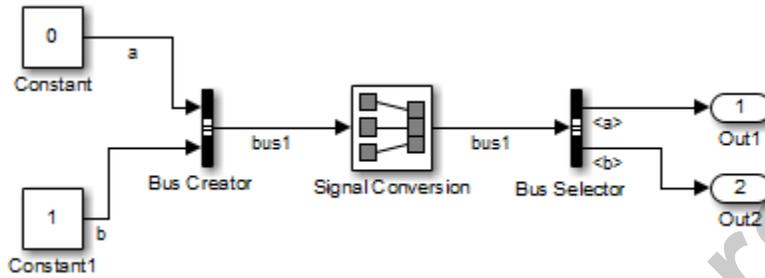

Type of Input Signal	Conversion that the Signal Copy Option Performs
	contiguous area of memory for the elements of the muxed signal and copies the values from the discontinuous areas (represented by the block's input) to the contiguous areas (represented by the block's output) at each time step.
Bus signal	Outputs a contiguous copy of the bus signal that is the input to the Signal Conversion block.

For an array of buses input signal, use the **Signal copy** option.

In the following example, a muxed signal inputs to a Signal Conversion block that has the **Output** parameter set to **Signal copy**. The Signal Conversion block converts the input signal to a vector.

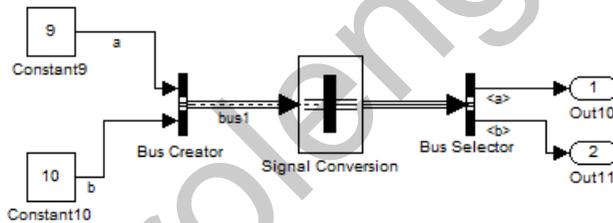

In the following example, a nonvirtual bus signal from a Bus Creator block inputs to a Signal Conversion block that has **Output** set to **Signal copy**. The Signal Conversion block creates another contiguous copy of the input bus signal.

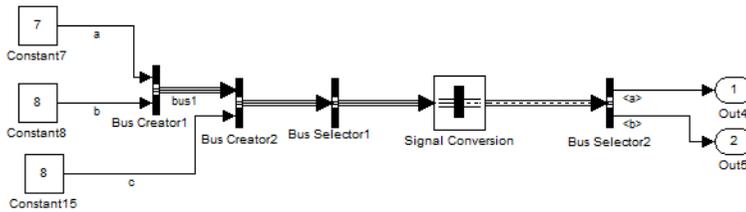

- The `Virtual bus` option converts a nonvirtual bus to a virtual bus.

In the following example, a Bus Creator block inputs to a Signal Conversion block that has **Output** set to `Virtual bus`. The Signal Conversion block converts the nonvirtual bus signal from the Bus Creator block to a virtual bus signal that inputs to the Bus Selector block.

- The `Nonvirtual bus` option converts a virtual bus to a nonvirtual bus.

In the following example, the Signal Conversion block converts a virtual bus signal from the first Bus Selector block to a nonvirtual bus signal that inputs to the second Bus Selector block. The Signal Conversion block has its **Output** parameter set to `Nonvirtual bus`, and specifies a bus object that matches the bus signal hierarchy of the bus that the first Bus Creator block outputs.

## Data type

Specify the output data type of the nonvirtual bus that the Signal Conversion block produces.

This option is available only when you set the **Output** parameter to **Nonvirtual bus**.

The default option is **Inherit: auto**, which uses a rule that inherits a data type.

You must specify a Simulink.Bus object in the **Data type** parameter for one or both of the following blocks:

- Signal Conversion block
- An upstream **Bus Creator** block

If you specify a bus object for the Signal Conversion block, but not for its upstream Bus Creator block, then use a bus object that matches the hierarchy of the bus that upstream Bus Creator block outputs.

If you specify a bus object for both the Signal Conversion block and its upstream Bus Creator block, use the same bus object for both blocks.

You can select the button to the right of the Data type parameter to open the Data Type Assistant, which helps you to set the **Data type** parameter.

See “Control Signal Data Types” in Simulink User's Guide for more information.

## Exclude this block from 'Block reduction' optimization

This option is available only when you set the **Output** parameter to **Signal copy**.

If the elements of the input signal occupy contiguous areas of memory, then as an optimization, Simulink software eliminates the block from the compiled model .

If you select the **Exclude this block from 'Block reduction' optimization**

check box, the optimization occurs the next time you compile the model. For more information, see “Block reduction”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block

# Signal Generator

Generate various waveforms

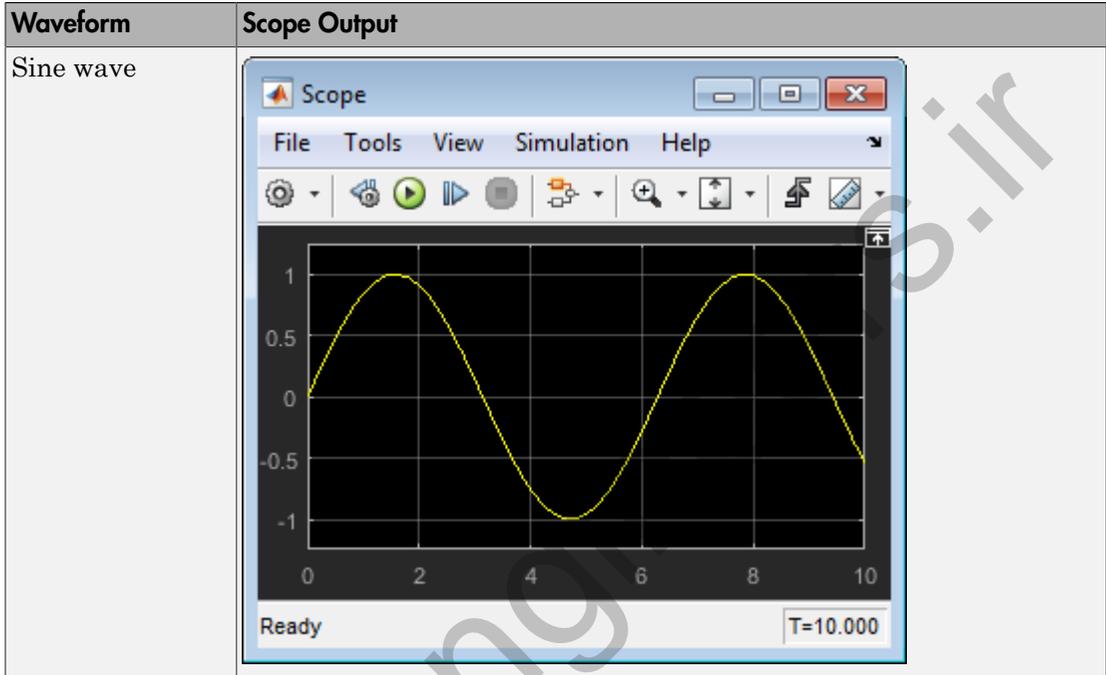

## Library

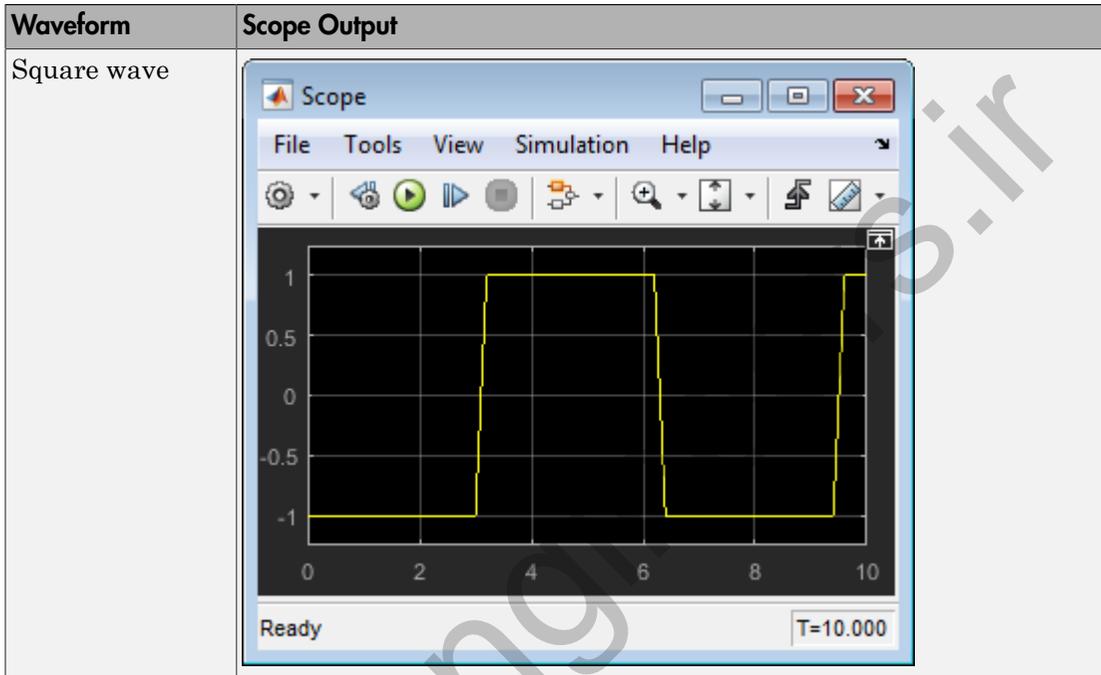

Sources

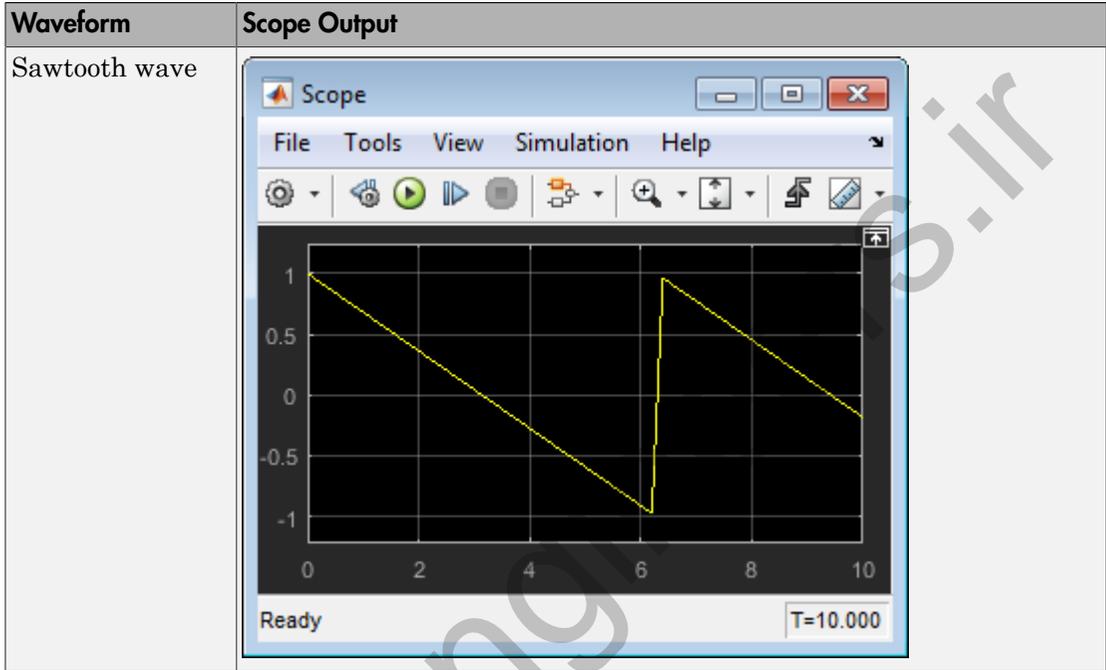

## Description

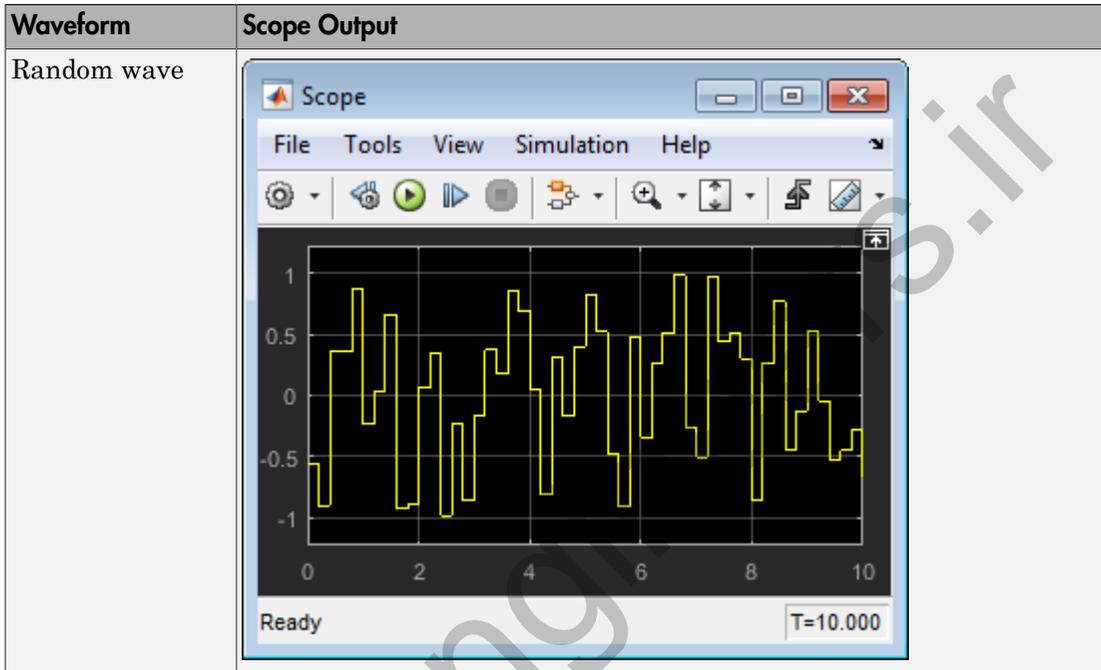

### Supported Operations

The Signal Generator block can produce one of four different waveforms: sine wave, square wave, sawtooth wave, and random wave. You can express signal parameters in Hertz (the default) or radians per second. Using default parameter values, you get one of the following waveforms:

Controlengineers.ir

A negative **Amplitude** parameter value causes a 180-degree phase shift. You can generate a phase-shifted wave at other than 180 degrees in many ways. For example, you can connect a Clock block signal to a MATLAB Function block and write the equation for the specific wave.

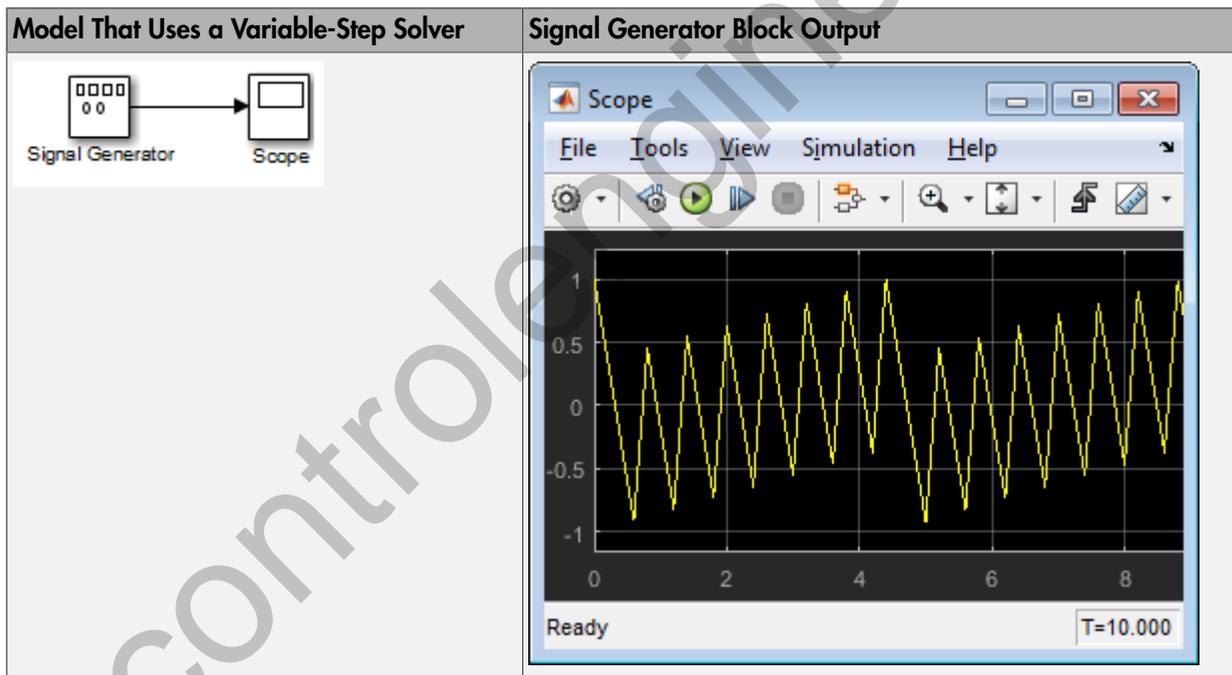

You can vary the output settings of the Signal Generator block while a simulation is in progress. This is useful to determine quickly the response of a system to different types of inputs.

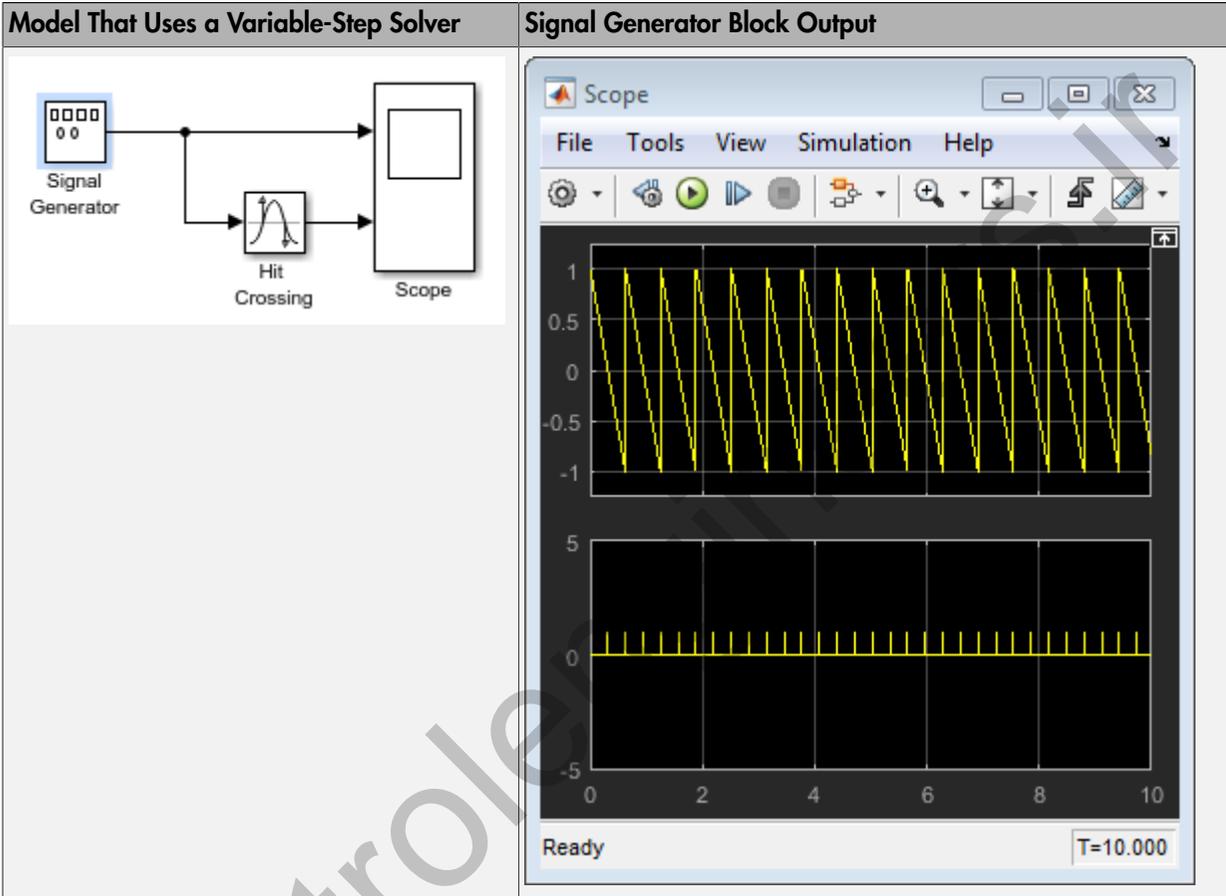

The **Amplitude** and **Frequency** parameters determine the amplitude and frequency of the output signal. The parameters must be of the same dimensions after scalar expansion. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensions as the **Amplitude** and **Frequency** parameters (after scalar expansion). If you select the **Interpret vector parameters as 1-D** check box, the block outputs a vector (1-D) signal if the **Amplitude** and **Frequency** parameters are row or column vectors, that is, single row or column 2-D arrays. Otherwise, the block outputs a signal of the same dimensions as the parameters.

## Solver Considerations

If your model uses a fixed-step solver, Simulink uses the same step size for the entire simulation. In this case, the Signal Generator block output provides a uniformly sampled representation of the ideal waveform.

If your model uses a variable-step solver, Simulink might use different step sizes during the simulation. In this case, the Signal Generator block output does not always provide a uniformly sampled representation of the ideal waveform. To ensure that the block output is a uniformly sampled representation, add a Hit Crossing block directly downstream of the Signal Generator block. The following models show the difference in Signal Generator block output with and without the Hit Crossing block.

## Data Type Support

The Signal Generator block outputs a scalar or array of real signals of type double.

For more information, see “Data Types Supported by Simulink”.

## Parameters

Wave form

Specify the wave form: a sine wave, square wave, sawtooth wave, or random wave. The default is a sine wave. This parameter cannot change while a simulation is running.

### Time

Specify whether to use simulation time as the source of values for the waveform's time variable or an external signal. If you specify an external time source, the block displays an input port for the time source.

### Amplitude

Specify the signal amplitude. The default is 1.

### Frequency

Specify the signal frequency. The default is 1.

### Units

Specify the signal units as Hertz or rad/sec. The default is rad/sec.

### Interpret vector parameters as 1-D

If selected, column or row matrix values for the **Amplitude** and **Frequency** parameters result in a vector output signal (see “Determining the Output Dimensions of Source Blocks”). This option is not available when an external signal specifies time. In this case, if the **Amplitude** and **Frequency** parameters are column or row matrix values, the output is a 1-D vector.

## Examples

The following Simulink examples show how to use the Signal Generator block:

- sldemo\_dbldcart1
- slexAircraftExample
- penddemo

## Characteristics

Data Types	Double

## Signal Specification

Specify desired dimensions, sample time, data type, numeric type, and other attributes of signal

## Library

Signal Attributes

## Description

The Signal Specification block allows you to specify the attributes of the signal connected to its input and output ports. If the specified attributes conflict with the attributes specified by the blocks connected to its ports, Simulink software displays an error when it compiles the model. For example, at the beginning of a simulation, if no conflict exists, Simulink eliminates the Signal Specification block from the compiled model. In other words, the Signal Specification block is a virtual block. It exists only to specify the attributes of a signal and plays no role in the simulation of the model.

You can use the Signal Specification block to ensure that the actual attributes of a signal meet desired attributes. For example, suppose that you and a colleague are working on different parts of the same model. You use Signal Specification blocks to connect your part of the model with your colleague's. If your colleague changes the attributes of a signal without informing you, the attributes entering the corresponding Signal Specification block do not match. When you try to simulate the model, you get an error.

You can also use the Signal Specification block to ensure correct propagation of signal attributes throughout a model. The capability of allowing the Simulink to propagate attributes from block to block is powerful. However, if some blocks have unspecified attributes for the signals they accept or output, the model does not have enough information to propagate attributes correctly. For these cases, the Signal Specification block is a good way of providing the information Simulink needs. Using the Signal

Specification block also helps speed up model compilation when blocks are missing signal attributes.

The Signal Specification block supports signal label propagation.

## Data Type Support

The Signal Specification block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types, as well as bus objects. The input data type must match the data type specified by the **Data type** parameter.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

---

For more information, see “Data Types Supported by Simulink”.

Controlengineers.ir

## Minimum

Specify the minimum value for the block output.

### Settings

**Default:** [] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see Simulink.BusElement.

---

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** Any valid finite real double scalar value

**Default:** '[]'

## Maximum

Specify the maximum value for the block output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

---

**Note:** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see Simulink.BusElement.

---

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** Any valid finite real double scalar value

**Default:** ' [ ] '

## Data type

Specify the output data type.

### Settings

**Default:** auto

**Inherit:** auto

Inherits the data type.

**double**

Specifies the data type is `double`.

**single**

Specifies the data type is `single`.

**int8**

Specifies the data type is `int8`.

**uint8**

Specifies the data type is `uint8`.

**int16**

Specifies the data type is `int16`.

**uint16**

Specifies the data type is `uint16`.

**int32**

Specifies the data type is `int32`.

**uint32**

Specifies the data type is `uint32`.

**boolean**

Specifies the data type is `boolean`.

**fixdt(1,16,0)**

Specifies the data type is fixed point `fixdt(1,16,0)`.

**fixdt(1,16,2^0,0)**

Specifies the data type is fixed point `fixdt(1,16,2^0,0)`.

**Enum:** <class name>

Specifies the data type as enumerated.

**Bus:** <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

### Dependency

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameters.

### Command-Line Information

**Parameter:** OutDataTypeStr

**Type:** character vector

**Value:** 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | <data type expression>

**Default:** 'Inherit: auto'

### See Also

“Control Signal Data Types”.

## Show data type assistant

Display the **Data Type Assistant**.

### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables auto.

#### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Specifies fixed-point data types.

#### Enumerated

Specifies enumerated data types. Selecting **Enumerated** enables you to enter a class name.

#### Bus

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

### Dependency

Clicking the **Show data type assistant** button  enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

“Specify Data Types Using Data Type Assistant”.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data signed or unsigned.

### Settings

**Default:** Signed

Signed

Specifies fixed-point data as signed.

Unsigned

Specifies the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

“Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

“Specifying a Fixed-Point Data Type”.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

“Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

“Specifying a Fixed-Point Data Type”.

## **Bias**

Specify bias for the fixed-point data type.

### **Dependencies**

Selecting **Scaling > Slope** and **bias** enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

“Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Require nonvirtual bus

If you specify a bus object as the data type, use this parameter to specify whether to accept only nonvirtual bus signals.

### Settings

**Default:** off

Off

Specifies that a signal must come from a *virtual* bus.

On

Specifies that a signal must come from a *nonvirtual* bus.

### Dependencies

The following **Data type** values enable this parameter:

- Bus: <object name>
- <data type expression> that specifies a bus object

### Command-Line Information

**Parameter:** BusOutputAsStruct

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Unit (e.g., m, m/s<sup>2</sup>, N\*m)

Specify physical unit of the input signal to the block.

### Settings

**Default:** inherit

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a **Unit System Configuration** block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a **Unit System Configuration** block does not exist in the component, the **Model Configuration Parameters** dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Dimensions (-1 for inherited)

Specify the dimensions of the input and output signals.

### Settings

**Default:** -1

-1

Specifies that signals inherit dimensions.

n

Specifies vector signal of width n.

[m n]

Specifies matrix signal having m rows and n columns.

### Command-Line Information

**Parameter:** Dimensions

**Type:** character vector

**Value:** '-1' | n | [m n]

**Default:** '-1'

## Variable-size signal

Specify a variable-size signal, fixed-size signal, or both.

### Settings

**Default:** Inherit

Inherit

Allows variable-size and fixed-size signals.

No

Does not allow variable-size signals.

Yes

Allows only variable-size signals.

### Dependencies

When the signal is a variable-size signal, the **Dimensions** parameter specifies the maximum dimensions of the signal.

If you specify a bus object, the simulation allows variable-size signals only with a disabled bus object.

### Command-Line Information

**Parameter:** VarSizeSig

**Type:** character vector

**Value:** 'Inherit' | 'No' | 'Yes'

**Default:** 'Inherit'

### See Also

“Variable-Size Signal Basics”

## Sample time (-1 for inherited)

Specify the time interval when simulation updates the block.

### Settings

**Default:** -1

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

### Command-Line Information

**Parameter:** SampleTime

**Type:** character vector

**Value:** Any valid sample time

**Default:** '-1'

### See Also

“Specify Sample Time”

Controlengineers.ir

## Signal type

Specify the numeric type of the input and output signals.

### Settings

**Default:** auto

auto

Accepts either `real` or `complex` as the numeric type.

real

Specifies the numeric type as a real number.

complex

Specifies the numeric type as a complex number.

### Command-Line Information

**Parameter:** SignalType

**Type:** character vector

**Value:** 'auto' | 'real' | 'complex'

**Default:** 'auto'

## Bus Support

The Signal Specification block supports virtual and nonvirtual buses. If you specify a bus object as the data type, then set these other block parameters as follows:

Block Parameter	Required Value for a Bus Data Type
Variable-size signal	No

All elements of the bus input to a Signal Specification block must have the same names as specified in the bus object.

All signals in a nonvirtual bus input to a Signal Specification block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

## Characteristics

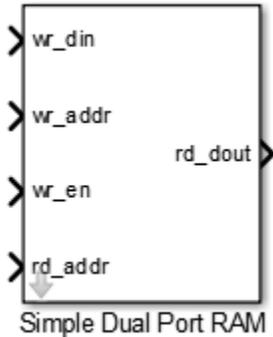

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified by the <b>Sample time</b> parameter
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

## Simple Dual Port RAM

Dual port RAM with single output port

### Library

HDL Coder / HDL Operations

### Description

The Simple Dual Port RAM block models RAM that supports simultaneous read and write operations, and has a single output port for read data. You can use this block to generate HDL code that maps to RAM in most FPGAs.

The Simple Dual Port RAM is similar to the Dual Port RAM, but the Dual Port RAM has both a write data output port and a read data output port.

### Read-During-Write Behavior

During a write operation, if a read operation occurs at the same address, old data appears at the output.

## Parameters

### Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

## Ports

The block has the following ports:

### wr\_din

Write data input. The data can have any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

### wr\_addr

Write address.

Data type: scalar unsigned integer (uintN) or unsigned fixed point (ufixN) with a fraction length of 0

### wr\_en

Write enable.

Data type: Boolean

### rd\_addr

Read address.

Data type: scalar unsigned integer (uintN) or unsigned fixed point (ufixN) with a fraction length of 0

### rd\_dout

Output data from read address, rd\_addr.

# Simulink Function

Function defined with Simulink blocks

**Library:** User-Defined Functions

## Description

The Simulink Function block is a **Subsystem** block preconfigured as a starting point for graphically defining a function with Simulink blocks. The block provides a text interface to function callers. You can call a Simulink Function block from a Function Caller block, a MATLAB Function block, or a Stateflow Chart.

For a description of the block parameters, see the **Subsystem** block reference page in the Simulink documentation.

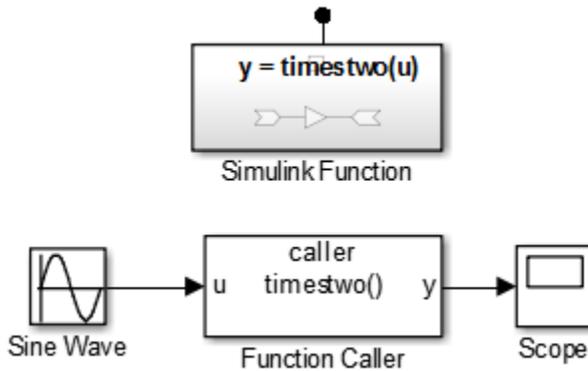

You can visualize Simulink Function calls in the Message Viewer. The viewer shows when calls were made with the argument and the return values. See Message Viewer block reference.

## Function Interface

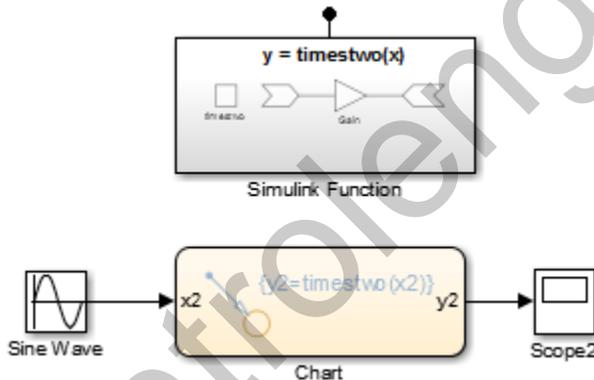

The function interface appears on the face of a Simulink Function block. Editing the block text adds and deletes **Argument Inport** blocks and **Argument Outport** blocks from the function definition. Editing also sets the **Function name** parameter in the **Trigger** block within the Simulink Function block.

For example, entering `y = myfunction(u)` on the face of a Simulink Function block adds one **Argument Inport** block (**u**) and one **Argument Outport** block (**y**) within the subsystem.

When calling a function using a Function Caller block, the parameter **Function prototype** in the Function Caller block must match exactly the function interface you specify on the Simulink Function block. This match includes the name of the function and the names of input and output arguments. For example, the Simulink Function block and the Function Caller block both use the argument names **u** and **y**.

When calling a function from a Stateflow transition or state label, you can use different argument names. For example, the Simulink Function block uses `x` and `y` arguments while the Stateflow transition uses `x2` and `y2` arguments to call the function.

## Function-Call Subsystems Versus Simulink Function Blocks

In general, a Function-Call Subsystem block provides better signal traceability with direct signal connections than a Simulink Function block. While a Simulink Function block eliminates the need for routing input and output signal lines through the model hierarchy.

Attribute	Function-Call Subsystem block	Simulink Function block
Method of executing/invoking function	Triggered using a signal line	Called by reference using the function name
Formal input arguments (Argument Inport blocks) and output arguments (Argument Outport blocks)	No	Yes
Local inputs (Inport block) and outputs (Outport block)	Yes	Yes

## Ports

### Input

#### **In — Signal input to a subsystem block**

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the Simulink Function block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment. See “Connect to Local Signals”.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### **ArgIn — Argument input to a subsystem block**

scalar | vector | matrix

An Argument Inport block in a subsystem block provides an input port corresponding to an input argument. A port is not displayed on the subsystem block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

## Output

### Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment. See “Connect to Local Signals”.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

### ArgOut — Argument output from a subsystem block

scalar | vector | matrix

An Argument Outport block in a subsystem block provides an output port corresponding to an output argument. A port is not displayed on the subsystem block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

# Single Port RAM

Single port RAM

## Library

HDL Coder / HDL Operations

## Description

The Single Port RAM block models RAM that supports sequential read and write operations.

If you want to model RAM that supports simultaneous read and write operations, use the Dual Port RAM or Simple Dual Port RAM.

## Parameters

### Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

### Output data during write

Controls the output data, `dout`, during a write access.

- **New data** (default): During a write, new data appears at the output port, `dout`.
- **Old data**: During a write, old data appears at the output port, `dout`.

## Ports

The block has the following ports:

`din`

Data input. The data can have any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr`

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we`

Write enable.

Data type: Boolean

`dout`

Output data from address, `addr`.

## Sine, Cosine

Implement fixed-point sine or cosine wave using lookup table approach that exploits quarter wave symmetry

## Library

Lookup Tables (Sine block or Cosine block)

## Description

The Sine and Cosine block implements a sine and/or cosine wave in fixed point using a lookup table method that exploits quarter wave symmetry.

The Sine and Cosine block can output the following functions of the input signal, depending upon what you select for the **Output formula** parameter:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$  and  $\cos(2\pi u)$

You define the number of lookup table points in the **Number of data points for lookup table** parameter. The block implementation is most efficient when you specify the lookup table data points to be  $(2^n)+1$ , where  $n$  is an integer.

**Tip:** To obtain meaningful block output, the block input values should fall within the range  $[0, 1)$ . For input values that fall outside this range, the values are cast to an

unsigned data type, where overflows wrap. For these out-of-range inputs, the block output might not be meaningful.

---

Use the **Output word length** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

## Data Type Support

The Sine and Cosine block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Output formula

Select the signal(s) to output.

### Number of data points for lookup table

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be  $(2^n)+1$ , where  $n$  is an integer.

### Output word length

Specify the word length for the fixed-point data type of the output signal. The fraction length of the output is the output word length minus 2.

---

**Note:** The block uses double-precision floating-point values to construct lookup tables. Therefore, the maximum amount of precision you can achieve in your output

is 53 bits. Setting the word length to values greater than 53 bits does not improve the precision of your output.

---

### Internal rule priority for lookup table

Specify the internal rule for intermediate calculations. Select **Speed** for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

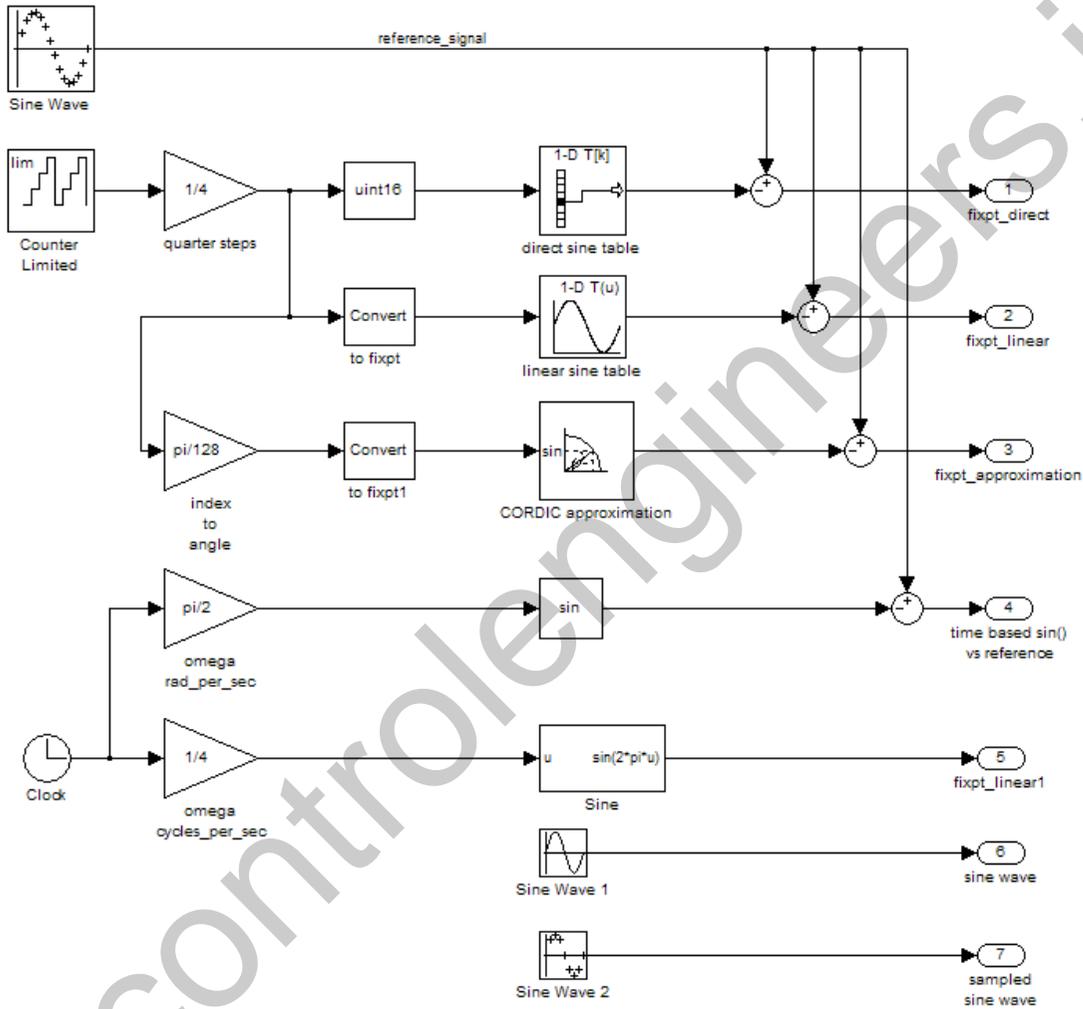

### Examples

The `sldemo_tongen_fixpt` model shows how you can use the Sine block to implement a fixed-point sine wave.

Controlengineers.ir

1 Blocks – Alphabetical List

Additional blocks to calculate sine and approximate sine using various algorithms.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point

Introduced before R2006a

## Sine HDL Optimized

Implement fixed-point sine wave by using lookup table approach that exploits quarter wave symmetry

### Library

HDL Coder / Lookup Tables

### Description

The Sine HDL Optimized block implements a fixed-point sine wave by using a lookup table method that exploits quarter-wave symmetry.

You define the number of lookup table points in the **Number of data points** parameter. The block implementation is most efficient for HDL code generation when you specify the lookup table data points to be  $(2^n)$ , where  $n$  is an integer. For information about the behavior of this block in HDL Coder, see Sine HDL Optimized.

Depending on your selection of the **Output formula** parameter, the blocks can output these functions of the input signal:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$  and  $\cos(2\pi u)$

Use the **Table data type** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

## Data Type Support

The Sine HDL Optimized block accepts signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Output formula

Select the signal(s) to output.

### Number of data points

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be  $(2^n)$ , where  $n$  is an integer.

### Table data type

Specify the table data type. You can specify an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

### Show data type assistant

Display the **Data Type Assistant**. In the **Data Type Assistant**, you can select the mode to specify the data type.

### Mode

Select the mode of data type specification. If you select **Expression**, enter an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

If you select **Fixed point**, you can use the options in the **Data Type Assistant** to specify the fixed-point data type. In the **Fixed point** mode, you can choose binary point scaling, and specify the signedness, word length, fraction length, and the data type override setting.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Sine Wave

Generate sine wave, using simulation time as time source

## Library

Sources

## Description

The Sine Wave block outputs a sinusoidal waveform. The block can operate in time-based or sample-based mode.

---

**Note:** This block is the same as the **Sine Wave Function** block that appears in the Math Operations library. If you select **Use external signal** for the **Time** parameter in the block dialog box, you get the Sine Wave Function block.

---

## Time-Based Mode

The output of the Sine Wave block is determined by:

$$y = \textit{amplitude} \times \sin(\textit{frequency} \times \textit{time} + \textit{phase}) + \textit{bias}.$$

Time-based mode has two submodes: continuous mode or discrete mode. The value of the **Sample time** parameter determines whether the block operates in continuous mode or discrete mode:

- 0 (the default) causes the block to operate in continuous mode.
- >0 causes the block to operate in discrete mode.

See “Specify Sample Time” in the online documentation for more information.

### Block Behavior in Continuous Mode

A **Sample time** parameter value of 0 causes the block to operate in continuous mode. When operating in continuous mode, the Sine Wave block can become inaccurate due to loss of precision as time becomes very large.

### Block Behavior in Discrete Mode

A **Sample time** parameter value greater than zero causes the block to behave as if it were driving a Zero-Order Hold block whose sample time is set to that value.

Using the Sine Wave block in this way, you can build models with sine wave sources that are purely discrete, rather than models that are hybrid continuous/discrete systems. Hybrid systems are inherently more complex and as a result take more time to simulate.

In discrete mode, this block uses a differential incremental algorithm instead of one based on absolute time. As a result, the block can be useful in models intended to run for an indefinite length of time, such as in vibration or fatigue testing.

The differential incremental algorithm computes the sine based on the value computed at the previous sample time. This method uses the following trigonometric identities:

$$\begin{aligned}\sin(t + \Delta t) &= \sin(t)\cos(\Delta t) + \sin(\Delta t)\cos(t) \\ \cos(t + \Delta t) &= \cos(t)\cos(\Delta t) - \sin(t)\sin(\Delta t)\end{aligned}$$

In matrix form, these identities are:

$$\begin{bmatrix} \sin(t + \Delta t) \\ \cos(t + \Delta t) \end{bmatrix} = \begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Because  $\Delta t$  is constant, the following expression is a constant:

$$\begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix}$$

Therefore, the problem becomes one of a matrix multiplication of the value of  $\sin(t)$  by a constant matrix to obtain  $\sin(t + \Delta t)$ .

Discrete mode reduces but does not eliminate the accumulation of round-off errors, for example,  $(4 \cdot \epsilon)$ . This accumulation can happen because computation of the block output at each time step depends on the value of the output at the previous time step.

### Methods to Handle Round-Off Errors in Discrete Mode

To handle round-off errors when the Sine Wave block operates in time-based discrete mode, use one of the following methods.

Method	Rationale
Insert a <b>Saturation</b> block directly downstream of the Sine Wave block.	By setting saturation limits on the Sine Wave block output, you can remove overshoot due to accumulation of round-off errors.
Set up the Sine Wave block to use the <b>sin()</b> math library function to calculate block output. <ol style="list-style-type: none"> <li><b>1</b> On the Sine Wave block dialog box, set <b>Time to Use external signal</b> so that an input port appears on the block icon.</li> <li><b>2</b> Connect a clock signal to this input port using a <b>Digital Clock</b> block.</li> <li><b>3</b> Set the sample time of the clock signal to the sample time of the Sine Wave block.</li> </ol>	Unlike the block algorithm, the <b>sin()</b> math library function computes block output at each time step <i>independently</i> of output values from other time steps, preventing the accumulation of round-off errors.

### Sample-Based Mode

Sample-based mode uses the following formula to compute the output of the Sine Wave block.

$$y = A \sin(2\pi(k + o) / p) + b$$

where

- $A$  is the amplitude of the sine wave.
- $p$  is the number of time samples per sine wave period.

- $k$  is a repeating integer value that ranges from 0 to  $p-1$ .
- $o$  is the offset (phase shift) of the signal.
- $b$  is the signal bias.

In this mode, Simulink sets  $k$  equal to 0 at the first time step and computes the block output, using the preceding formula. At the next time step, Simulink increments  $k$  and recomputes the output of the block. When  $k$  reaches  $p$ , Simulink resets  $k$  to 0 before computing the block output. This process continues until the end of the simulation.

The sample-based method of computing block output at a given time step does not depend on the output of the previous time steps. Therefore, this mode avoids the accumulation of round-off errors. Additionally, sample-based mode supports reset semantics in subsystems that offer it. For example, if a Sine Wave block is in a resettable subsystem that receives a reset trigger, the repeating integer  $k$  resets and the block output resets to its initial condition.

## Parameter Dimensions

The numeric parameters of this block must have the same dimensions after scalar expansion.

- If **Interpret vector parameters as 1-D** is not selected, the block outputs a signal of the same dimensions and dimensionality as the parameters.
- If **Interpret vector parameters as 1-D** is selected and the numeric parameters are row or column vectors, the block outputs a vector signal. Otherwise, the block outputs a signal of the same dimensionality and dimensions as the parameters.

## Data Type Support

The Sine Wave block accepts and outputs real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

**Sine type**

Specify the type of sine wave that this block generates, either time- or sample-based. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

### Time

Specify whether to use simulation time as the source of values for the time variable or an external source. If you specify an external time source, the block displays an input port for the time source.

### Amplitude

Specify the amplitude of the signal. The default is 1.

### Bias

Specify the constant value added to the sine to produce the output of this block.

### Frequency

Specify the frequency, in radians per second. The default is 1. This parameter appears only when you set **Sine type** to time-based.

### Samples per period

Specify the number of samples per period. This parameter appears only when you set **Sine type** to sample-based.

### Phase

Specify the phase shift, in radians. The default is 0. This parameter appears only when you set **Sine type** to time-based.

You cannot configure this parameter to appear in the generated code as a tunable global variable if you set **Time (t)** to `Use simulation time`. For example, if you set **Default parameter behavior** to `Tunable` or apply a storage class to a `Simulink.Parameter` object, the **Phase** parameter does not appear in the generated code as a tunable global variable.

To generate code so that you can tune the phase during execution, set **Time (t)** to `Use external signal`. You can provide your own time input signal or use a Digital Clock block to generate the time signal. For an example, see “Tune Phase Parameter of Sine Wave Block During Code Execution” (Simulink Coder).

### Number of offset samples

Specify the offset (discrete phase shift) in number of sample times. This parameter appears only when you set **Sine type** to sample-based.

### Sample time

Specify the sample period. The default is 0. If the sine type is sample-based, the sample time must be greater than 0. See “Specify Sample Time” in the online documentation for more information.

**Interpret vector parameters as 1-D**

If selected, column or row matrix values for numeric parameters result in a vector output signal. Otherwise, the block outputs a signal of the same dimensionality as the parameters. If you do not select this check box, the block always outputs a signal of the same dimensionality as the numeric parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation. This parameter is not available when an external signal specifies time. In this case, if numeric parameters are column or row matrix values, the output is a 1-D vector.

**Examples**

The following Simulink examples show how to use the Sine Wave block:

- sldemo\_househeat
- sldemo\_tonegen\_fixpt
- sldemo\_VariableTransportDelay
- sldemo\_zeroxing

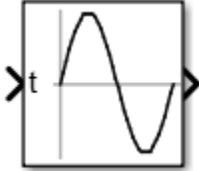

**Characteristics**

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

## Sine Wave Function

Generate sine wave, using external signal as time source

### Library

Math Operations

### Description

This block is the same as the **Sine Wave** block that appears in the Sources library. If you select **Use simulation time** for the **Time** parameter in the block dialog box, you get the Sine Wave block. See the documentation for the Sine Wave block for more information.

### Characteristics

Data Types	Double
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

## Slider

Set value on sliding scale to tune parameters or variables

## Library

Dashboard

## Description

The Slider block enables you to control the value of tunable parameters and variables in your model during simulation.

To control a tunable parameter or variable using the Slider block, double-click the Slider block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

The tick range determines the range of values available for the tunable parameter or variable. You can modify the tick range by modifying the **Minimum**, **Maximum**, and **Tick Interval** values.

## Limitations

The Slider block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

Limitation	Workaround
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### Scale Type

Type of scale to use for tuning.

### Settings

**Default:** Linear

Linear

Use linear scale.

Log

Use logarithmic scale.

## Minimum

Minimum tick mark value.

### Settings

**Default:** 0

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Minimum** tick value must be less than the **Maximum** tick value.

## Maximum

Maximum tick mark value.

### Settings

**Default:** 100

Specify this number as a finite, real, double, scalar value.

### Dependencies

The **Maximum** tick value must be greater than the **Minimum** tick value.

## Tick Interval

Interval between major tick marks.

### Settings

**Default:** auto

Specify this number as a finite, real, positive, integer, scalar value. Specify as **auto** for the block to adjust the tick interval automatically.

## Label

Position of the block label or instructional text if the block is not connected.

## Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015b**

## Slider Gain

Vary scalar gain using slider

### Library

Math Operations

### Description

Use the Slider Gain block to modify a scalar gain during a simulation using a slider. The block accepts one input and generates one output.

### Data Type Support

Data type support for the Slider Gain block is the same as that for the Gain block (see Gain).

### Parameters

#### Low

Specify the lower limit of the slider range. The default is 0.

#### High

Specify the upper limit of the slider range. The default is 2.

The edit fields indicate the lower limit and the upper limit. You can change the gain in two ways: by manipulating the slider, or by entering a new value in the current value field. You can change the range of gain values by changing the lower and upper limits.

To apply a vector or matrix gain to the block input, consider using the Gain block.

## Examples

The following example models show how to use the Slider Gain block:

- `aero_six_dof`

## Characteristics

Data Types	Double   Single   Boolean   Base Integer
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Gain

Introduced before R2006a

# Spectrum Analyzer

Display frequency spectrum of time-domain signals

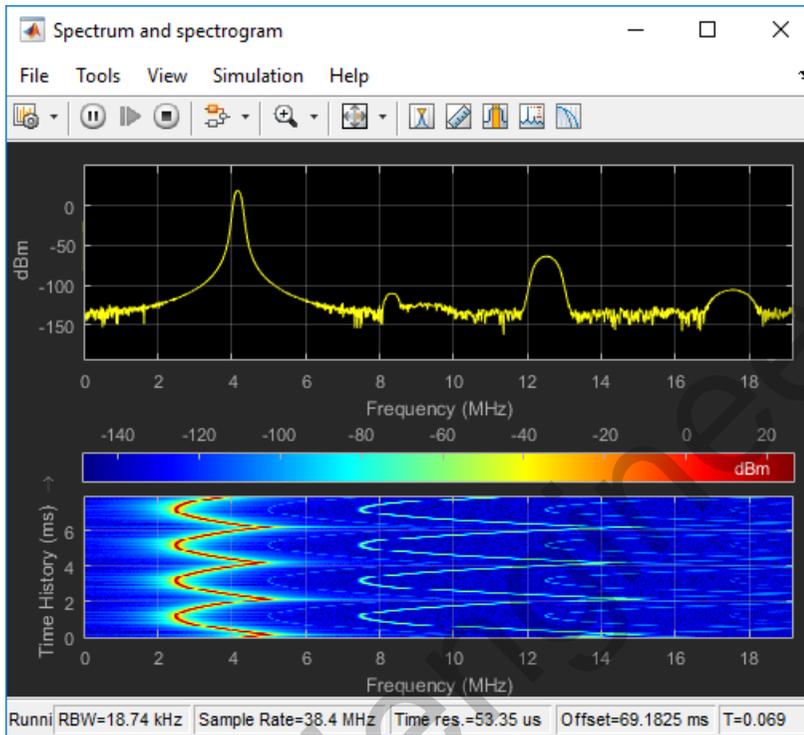

## Description

The Spectrum Analyzer block, referred to here as the scope, displays frequency spectra of signals. The Spectrum Analyzer block accepts input signals, through one or more input ports, with the following characteristics:

- Discrete sample time
- Real- or complex-valued
- Fixed number of channels of variable length
- Floating- or fixed-point data type

controlengineers.ir

You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations. See the “Supported Simulation Modes” on page 1-1730 section for more information.

You can use the Spectrum Analyzer block inside of all subsystems and conditional subsystems. *Conditional subsystems* include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditional Subsystems” for more information.

You can configure and display Spectrum Analyzer settings from the command line with `spbscopes.SpectrumAnalyzerConfiguration`.

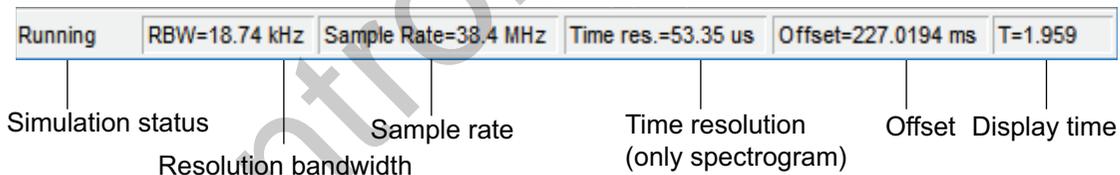

See the following sections for more information on the Spectrum Analyzer:

- “Signal Display” on page 1-1680
- “Spectrum Settings” on page 1-1687

- “Measurements Panels” on page 1-1695
- “Visuals — Spectrum Properties” on page 1-1709
- “Style Dialog Box” on page 1-1712
- “Tools — Axes Scaling Properties” on page 1-1713
- “Algorithms” on page 1-1717
- “Differences from Spectrum Scope Block” on page 1-1725
- “Supported Data Types” on page 1-1730
- “Supported Simulation Modes” on page 1-1730

## Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **Resolution Bandwidth**, **Time Resolution**, and **Offset** indicators on the status bar in the scope window for this information. These indicators relate to the Minimum Frequency-Axis limit and Maximum Frequency-Axis limit values on the *frequency*-axis of the scope window. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the Simulation Status and Simulation time indicators on the status bar in the scope window for this information. The following figure highlights these aspects of the Spectrum Analyzer window.

**Note:** To prevent the scope from opening when you run your model, right-click the scope icon and select **Comment Out**. If the scope is already open, and you comment it out in the

model, the scope displays, “No data can be shown because this scope is commented out.” Select **Uncomment** to turn the scope back on.

---

- *Frequency Span* — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

### Details

Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

- **Span** (Hz) and **CF** (Hz) visible — The *Frequency Span* value equals the **Span** parameter in the **Main options** pane.
- **FStart** (Hz) and **FStop** (Hz) — The frequency span value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula:  $f_{span} = f_{stop} - f_{start}$ .

By default, the **Full Span** check box in the **Main options** pane is enabled. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, the Nyquist interval is

$$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

- *Resolution Bandwidth* — The smallest positive frequency or frequency interval that can be resolved.

### Details

Spectrum Analyzer sets the resolution bandwidth using the value of the frequency resolution parameter on the **Main options** pane of the **Spectrum Settings** panel.

By default, this parameter is set to **RBW** (Hz) and 'Auto'. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified *Frequency Span*.

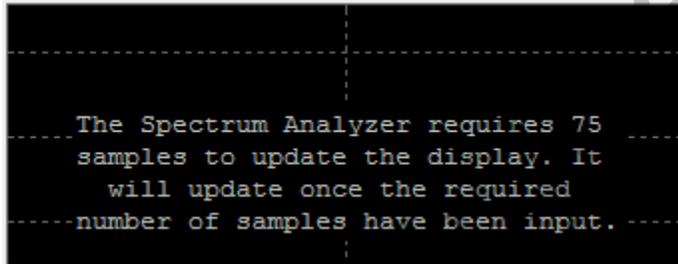

You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main**

**options** pane. This value is directly related to  $RBW$  by the following equation:

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

. Overlap percentage,  $O_p$ , is the value of the

**Overlap** % parameter in the **Window Options** pane of the **Spectrum Settings** panel.  $NENBW$  is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane.  $F_s$  is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

If the frequency resolution setting on the **Main options** pane of the **Spectrum Settings** is **Window length**, you specify the window length and the resulting  $RBW$  is  $\frac{NENBW * F_s}{N_{window}}$ . The **Samples/update** in this case is directly related to  $RBW$  by the

following equation: 
$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

- **Time Resolution** — The time resolution for a spectrogram line.

### Details

*Time resolution* is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. *Time Resolution* is displayed only when the spectrum **Type** is **Spectrogram**.

- *Offset* — The constant frequency offset to apply to the entire spectrum or a vector of frequency offsets to apply to each spectrum for multiple inputs.

### Details

Spectrum Analyzer adds this constant offset or the vector of offsets to the values on the *frequency*-axis using the value of **Offset** on the **Trace options** pane of the **Spectrum Settings** panel. The offset is the current time value at the middle of the interval of the line displayed at 0 seconds. The actual time of a particular spectrogram line is the offset minus the *y*-axis time listing. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters on the **Main options** pane of the **Spectrum Settings** panel to ensure that the frequency span is within Nyquist limits. The offset is displayed on the plot only when the spectrum **Type** is Spectrogram.

- *Simulation Status* — Provides the current status of the model simulation.

### Details

The status can be one of the following conditions:

- *Processing* — Occurs after you construct the **SpectrumAnalyzer** object.
- *Stopped* — Occurs after you run the release method.

The *Simulation Status* is part of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View > Status Bar**.

- *Display time* — The amount of time that has progressed since the last update to the Spectrum Analyzer display.

### Details

Every time data is processed by the block, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula:  $t_{sim} = t_{sim} + \frac{\text{length}(0:\text{length}(xsine))-1}{\text{SampleRate}}$ . When **Reduce Plot**

**Rate to Improve Performance** is checked, the simulation time and display time might differ. At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel.

The *Display time* indicator is a component of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View > Status Bar**.

For more information, see “Spectrum Settings” on page 1-1687.

## Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display at fixed intervals of time at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum Analyzer menu, select **Simulation > Reduce Plot Rate to Improve Performance** to clear the check box. Tunable.

---

**Note:** When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot Rate to Improve Performance** check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

---

## Spectral Masks

You can add upper and lower spectral mask lines to spectrum plots. You use spectral masks to enhance visualizing spectrum limits. Spectral masks also are useful for comparing spectrum values to specification values.

You must use commands at the MATLAB command line to setup or configure spectral masks for a Spectrum Analyzer block. You use `get_param` to create a Spectrum Analyzer configuration object to control the block. The configuration object has a `SpectralMask` property. The `SpectralMask` property uses `SpectralMaskSpecification` properties to enable and configure the spectral masks. The `SpectralMaskSpecification` properties, which are described in `spbscopes.SpectrumAnalyzerConfiguration`, are

- `EnabledMasks` — Turn on spectral mask.
- `UpperMask` — Set upper mask values.
- `LowerMask` — Set lower mask values.
- `ReferenceLevel` — Select the mask reference level to use a specific value or the spectrum peak value.
- `CustomReferenceLevel` — Set mask reference level value.
- `SelectedChannel` — Set channel to use for mask reference.
- `MaskFrequencyOffset` — Set frequency offset for mask.

You can check the status of the spectral mask using a method or an event listener.

- To get the status of the spectral masks, call `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

### Example of Spectral Mask

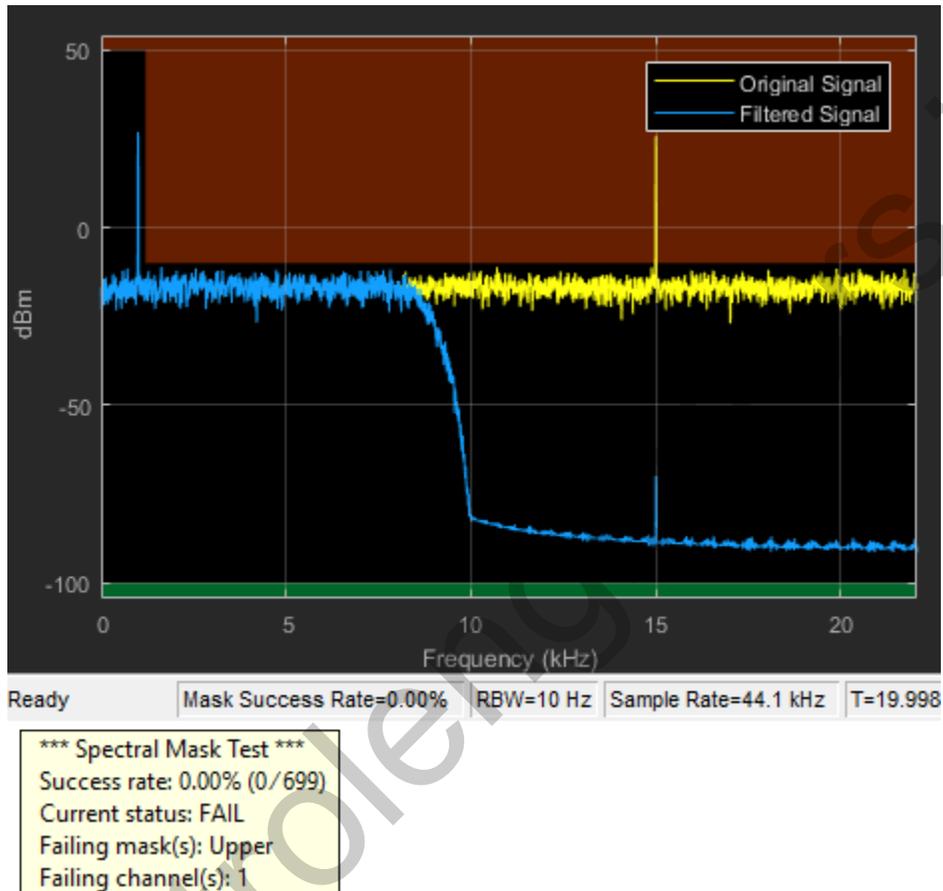

This example shows how to create a new model based on the `dsp_basic_filter` template, add a spectral mask to its Spectrum Analyzer block, and run the model.

```

[-,mdl] = fileparts(tempname);
open_system(new_system(mdl,'FromTemplate','dsp_basic_filter'));
saBlock = find_system(mdl,'BlockType','SpectrumAnalyzer');

scopeConfig = get_param(saBlock{1},'ScopeConfiguration');
upperMask = [0 50; 1200 50; 1200 -10; 24000 -10];
scopeConfig.SpectralMask.UpperMask = upperMask;
scopeConfig.SpectralMask.LowerMask = -100;
scopeConfig.SpectralMask.EnabledMasks = 'Upper and lower';

sim(mdl,'StopTime','20');
    
```

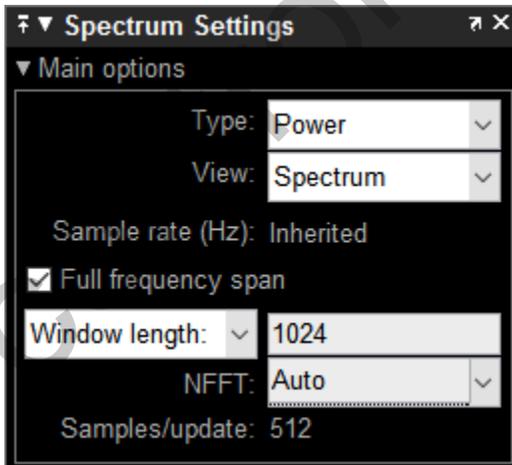

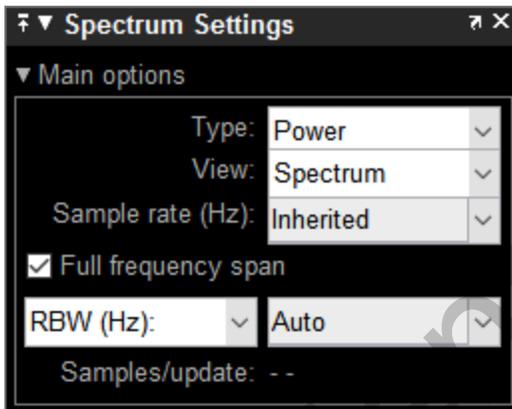

Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing.

At the bottom of the window, the **Mask success rate** shows what percentage of the time the mask is succeeding. A tooltip gives you details about which mask is failing, how many times the mask(s) failed, and which channels are causing the failure.

## Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View > Spectrum Settings**. Alternatively, in

the Spectrum Analyzer toolbar, select the Spectrum Settings  button.

The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Window Options**, and **Trace Options**. You can expand each pane to see the available options.

## Main Options Pane

The **Main Options** pane enables you to modify the main options.

- **Type** — The type of spectrum to display. Available options are **Power**, **Power density**, and **RMS**. When you set this parameter to **Power**, the Spectrum Analyzer shows the power spectrum. When you set this parameter to **Power density**, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz. When you set this parameter to **RMS**, the Spectrum Analyzer shows the root mean squared spectrum. Tunable
- **View** — The spectrum view to display. Available options are **Spectrum**, **Spectrogram**, and **Spectrum and spectrogram**. When you set this parameter to **Spectrum**, the Spectrum Analyzer shows the spectrum. When you set this parameter to **Spectrogram**, the Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display and time scrolls from the bottom to the top of the display. When you set this parameter to **Spectrum and spectrogram**, the Spectrum Analyzer shows both the spectrum and spectrogram. Tunable.
- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals. Select **Inherited** to use the same sample rate as the input signal. To specify a sample rate, enter its value.
- **Full frequency span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is  $\left[ \frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset}$  hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval is  $\left[ 0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset}$  hertz. Tunable.
- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and

center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency-axis* values using start frequency and stop frequency instead.

- **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency-axis* on the Spectrum Analyzer window. Tunable.
- **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency-axis* on the Spectrum Analyzer window. Tunable.
- **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency-axis* on the Spectrum Analyzer window. Tunable.
- **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency-axis* on the Spectrum Analyzer window. Tunable.
- **RBW (Hz) / Window length** — The frequency resolution method.

If set to **RBW (Hz)**, the resolution bandwidth, in hertz. This property defines the smallest positive frequency that can be resolved. By default, this property is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified frequency span.

If you set this property to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall frequency span to *RBW* must be at least two:  $\frac{span}{RBW} > 2$ .

Tunable.

If set to **Window length**, the length of the window, in samples, used to control the frequency resolution and compute the spectral estimates. The window length must be an integer scalar greater than 2.

Tunable.

The time resolution value is determined based on frequency resolution method, the *RBW* setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
RBW (Hz)	Auto	Auto	1/RBW s
RBW (Hz)	Auto	Manually entered	Time Resolution s
RBW (Hz)	Manually entered	Auto	1/RBW s
RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.
Window length	—	Auto	1/RBW s $RBW = (NENBW * F_s) / \text{Window Length}$ , where <i>NENBW</i> is the normalized effective noise bandwidth of the specified window.
Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, $(NENBW * F_s) / \text{Window Length}$ . Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

- **NFFT** — The number of Fast Fourier Transform (FFT) points. You can set the **NFFT** only when in Window length mode. This property defines the length of the FFT that

Spectrum Analyzer uses to compute spectral estimates. Acceptable options are **Auto** or a positive, scalar integer. The **NFFT** value must be greater than or equal to the **Window length**. By default, when **NFFT** is set to **Auto**, Spectrum Analyzer sets the number of FFT points to the window length. When in **RBW** mode, an FFT length is used that equals the window length required to achieve the specified **RBW** value.

When this property is set to a positive integer, this property is equivalent to the **n** parameter that you can set when you run the MATLAB `fft` function. Tunable.

- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this property; it is shown here for display purposes only. This property is directly related to **RBW** by the following equation:

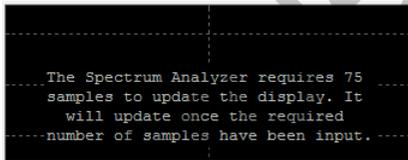

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

or to the window length by this equation:

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) \times WindowLength$$

*NENBW* is the normalized effective noise

bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane.  $F_s$  is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.

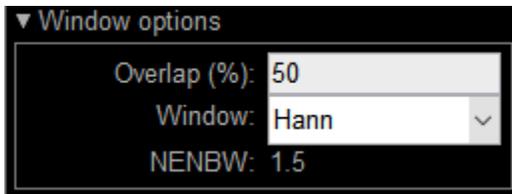

## Spectrogram Options Pane

- **Channel** — Select the signal channel for which the spectrogram settings apply. This option displays only when the **Type** is **Spectrogram** and only if there is more than one signal channel input.
- **Time res. (s)** — The time resolution, in seconds. Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings. This property applies only to spectrograms. Tunable

- **Time span (s)** — The time span over which the Spectrum Analyzer displays the spectrogram, in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to **Auto**, 100 spectral lines are used. This property applies only to spectrograms. Tunable

## Window Options Pane

The **Window Options** pane enables you to modify the window options.

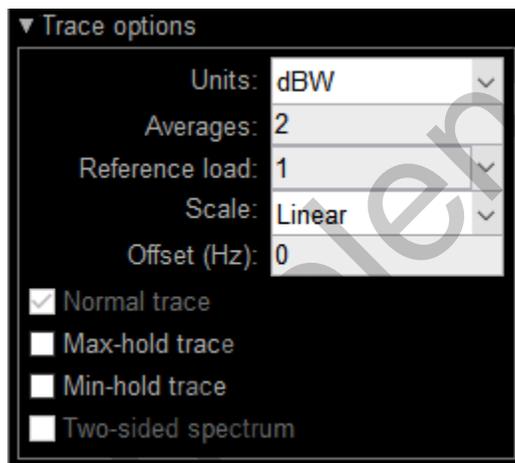

- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. Tunable.
- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows” (Signal Processing Toolbox). Tunable.
- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to **Chebyshev** or **Kaiser**. You must specify a value greater than or equal to 45. Tunable.
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation:

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[ \sum_{n=1}^{N_{window}} w(n) \right]^2}$$

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

## Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.

- **Units** — The units of the spectrum. The available values depends on the value of **Type**. Available options include dBm, dBW, Watts, Vrms, and dBV. Tunable.
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. This property applies only when the Spectrum **View** is **Spectrum** or **Spectrum** and **spectrogram**. Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last  $N$  power spectrum estimates. This property defines the number of spectral averages,  $N$ . Tunable.

- **Reference load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. Tunable.
- **Scale** — Linear or logarithmic scale. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. Tunable.
- **Offset** — The constant frequency offset to apply to the entire spectrum or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval is  $\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz if **Two-sided spectrum** is selected, and  $\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset$  hertz otherwise. Tunable
- **Normal trace** — Normal trace view. This property applies only when the Spectrum **View** is **Spectrum** or **Spectrum and spectrogram**. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. Tunable.
- **Max hold trace** — Maximum hold trace view. This property applies only when the Spectrum **View** is **Spectrum** or **Spectrum and spectrogram**. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. Tunable.
- **Min hold trace** — Minimum hold trace view. This property applies only when the Spectrum **View** is **Spectrum** or **Spectrum and spectrogram**. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. Tunable
- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

## Measurements Panels

The Measurements panels are the other four panels that appear to the right side of the Spectrum Analyzer figure.

### Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

### Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

---

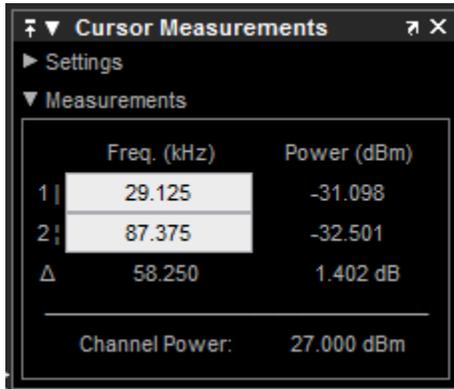

**Note:** If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

---

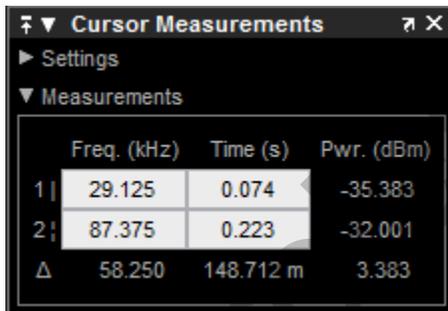

In the Scope menu, select **Tools > Measurements > Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel appears as follows for the spectrum and dual view.

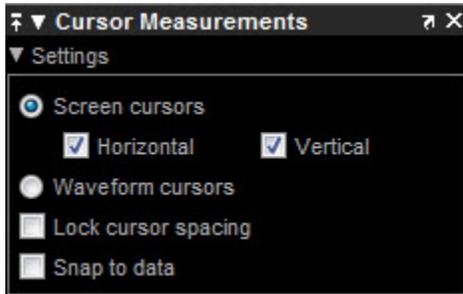

The **Cursor Measurements** panel appears as follows for the spectrogram view. You must pause the spectrogram display before you can use cursors.

The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

### Measurements Pane

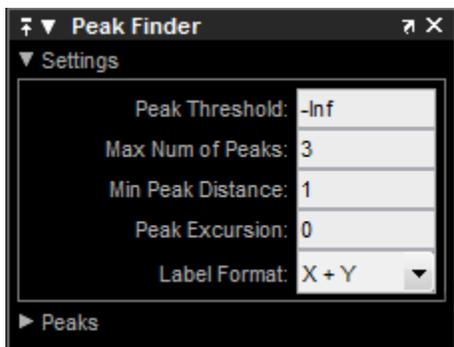

The **Measurements** pane displays the frequency (Hz) , time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

## Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the  $x$ -axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

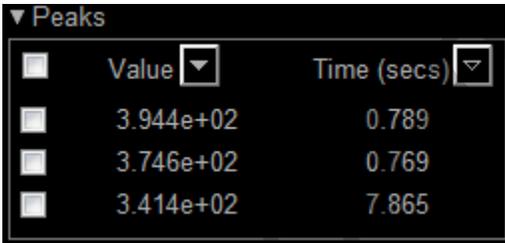

The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox™ `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.

- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. The peak excursion setting is equivalent to the **THRESHOLD** parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - **X+Y** — Display both *x*-axis and *y*-axis values.
  - **X** — Display only *x*-axis values.
  - **Y** — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

<input type="checkbox"/>	Value ▾	Time (secs) ▾
<input type="checkbox"/>	3.944e+02	0.789
<input type="checkbox"/>	3.746e+02	0.769
<input type="checkbox"/>	3.414e+02	7.865

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button (▾) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (▴). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled

() , then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

## Channel Measurements Panel

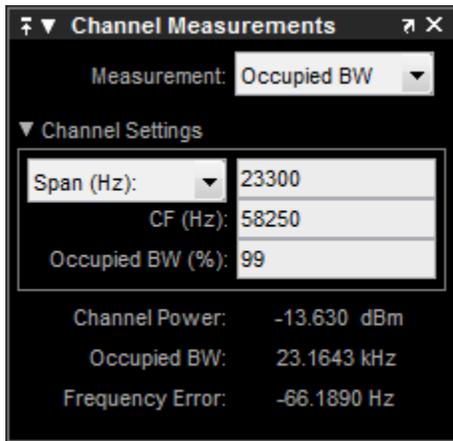

The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements. You can choose to hide or display this pane in the Scope menu by selecting **Tools > Measurements > Channel Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are **Occupied BW** or **ACPR**. See “Algorithms” on page 1-1717 for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select **Occupied BW** as the **Measurement**, the following fields appear.

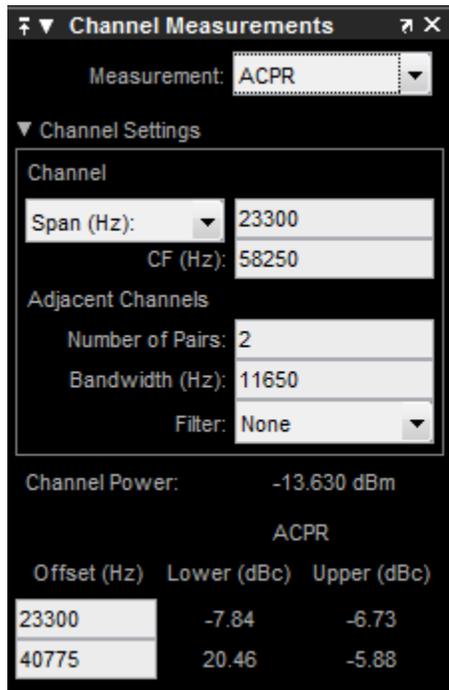

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

#### Channel Settings for Occupied BW

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select **Occupied BW** as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select **Occupied BW** as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

#### Channel Settings for ACPR

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Number of Pairs** — The number of pairs of adjacent channels.
- **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
- **Filter** — The filter to use for both main and adjacent channels. Available filters are **None**, **Gaussian**, and **RRC** (root-raised cosine).
- **Channel Power** — The total power in the channel.

- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.

## Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements. You can choose to hide or display this panel in the Scope menu by selecting **Tools > Measurements > Distortion Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements  button.

The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

---

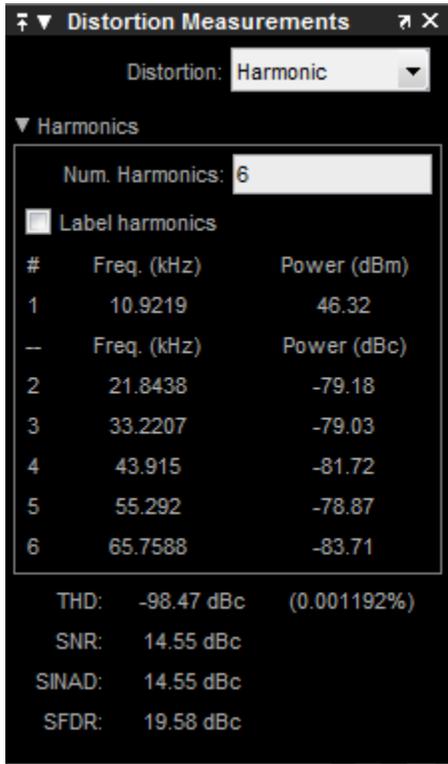

**Note:** For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

---

- **Distortion** — The type of distortion measurements to display. Available options are **Harmonic** or **Intermodulation**. Select **Harmonic** if your system input is a single sinusoid. Select **Intermodulation** if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

See “Algorithms” on page 1-1717 for information on how distortion measurements are calculated.

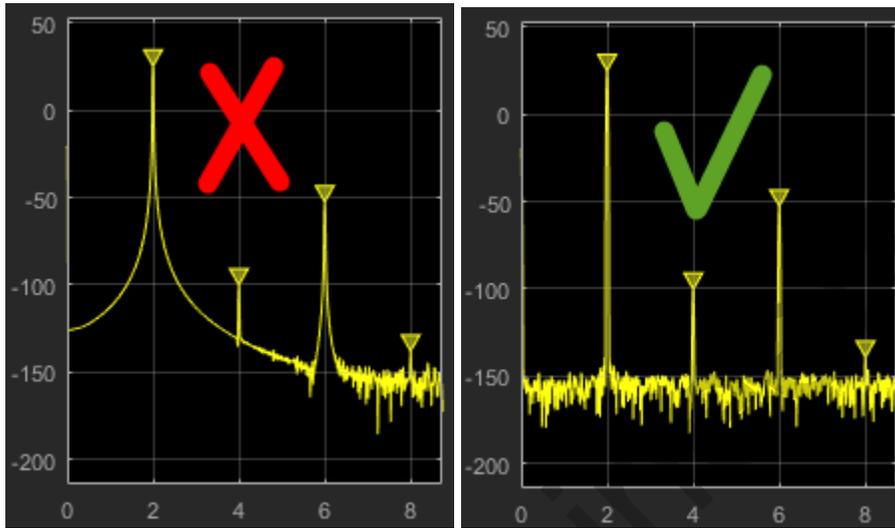

When you select **Harmonic** as the **Distortion**, the following fields appear.

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

**Note:** To best view the harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Additionally, the noise floor should be visible.

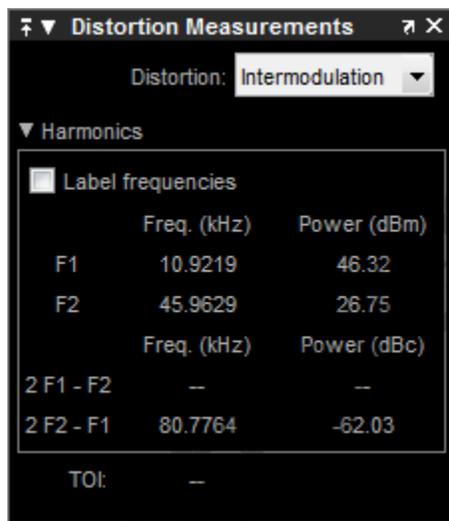

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to one milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics,  $D$ , to the power in the fundamental frequency,  $S$ . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.  
 $THD = 10\log_{10}(D/S)$ .
- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency,  $S$ , to the power of all nonharmonic content,  $N$ , including spurious signals, in decibels relative to the carrier (dBc).  $SNR = 10\log_{10}(S/N)$ . If you see -- as the reported SNR, your signal's total non-harmonic content is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency,  $S$  to all other content (including noise,  $N$ , and harmonic distortion,  $D$ ), in decibels relative to the carrier (dBc).  $SINAD = 10\log_{10}(S/(N + D))$ .
- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency,  $S$ , to power of the largest spurious signal,  $R$ , regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.  $SFDR = 10\log_{10}(S/R)$ .

When you select Intermodulation as the **Distortion**, the following fields appear.

The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products ( $2 * F1 - F2$  and  $2 * F2 - F1$ ).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency

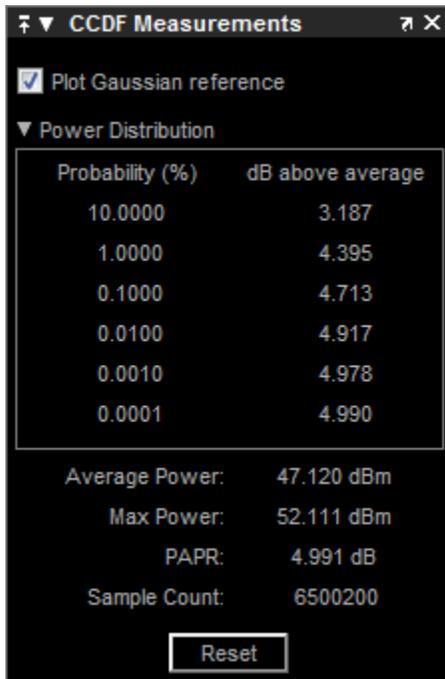

- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

## CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

You can choose to hide or display this panel in the Scope menu by selecting **Tools > Measurements > CCDF Measurements**. Alternatively, in the Scope toolbar, click the CCDF Measurements  button.

- **Plot Gaussian reference** — Select **Plot Gaussian reference** to show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.
- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.
- **Max Power** — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.

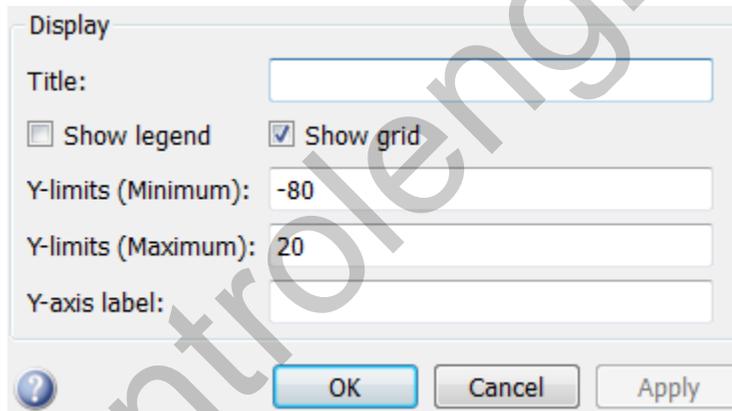

- **Reset** — Clear all current CCDF measurements and restart.

## Visuals — Spectrum Properties

The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View > Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties  button.

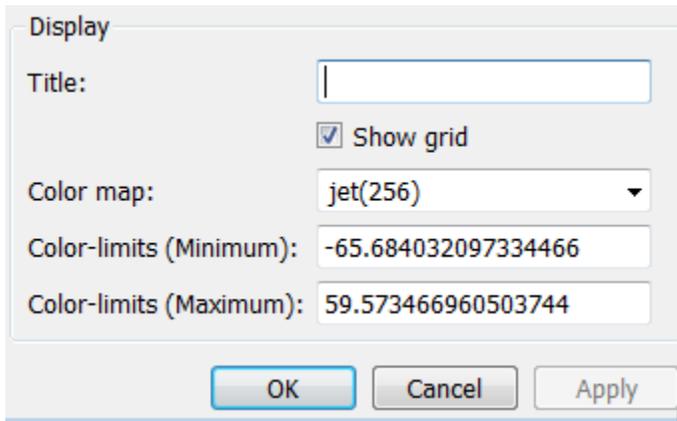

### Display Pane

When the Spectrum **View** is **Spectrum**, the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:

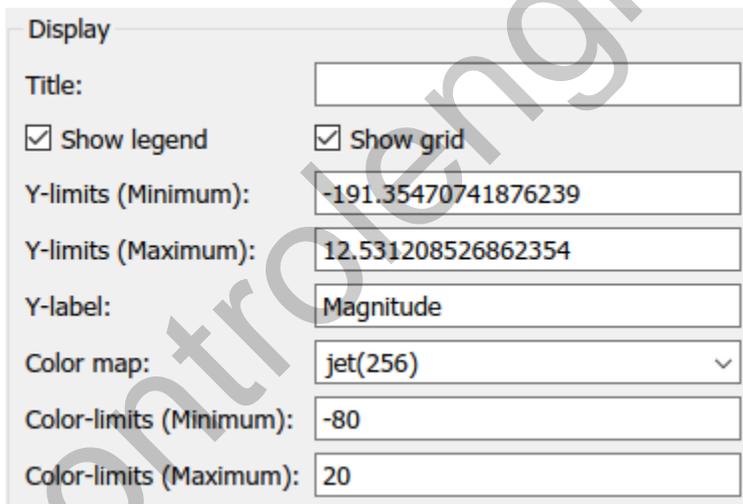

Display  
 Title:   
 Show legend  Show grid  
 Y-limits (Minimum):   
 Y-limits (Maximum):   
 Y-axis label:

When the Spectrum **View** is **Spectrogram** the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:

When the Spectrum **View** is Spectrum or spectrogram the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:

**Title**

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

By default, the display has no title.

## Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn off the legend, clear the **Show legend** check box.

You can edit the name of any channel in the legend by double-clicking the current name and entering a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

This parameter applies only when the **View Type** is **Spectrum** or **Spectrum** and spectrogram. Tunable

## Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable

## Y-limits (Minimum)

Specify the minimum value of the  $y$ -axis. Tunable

## Y-limits (Maximum)

Specify the maximum value of the  $y$ -axis. Tunable

## Y-axis label

Specify the text for the scope to display to the left of the  $y$ -axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of 'dBm', 'dBW', 'Watts', 'dBm/Hz', 'dBW/Hz', 'Watts/Hz',  $V_{rms}$ , or dBVTunable.

## Color map

Select the color map for the spectrogram, or enter a 3-column matrix expression for the color map. See `colormap` for information. Tunable.

**Color-limits (Minimum)**

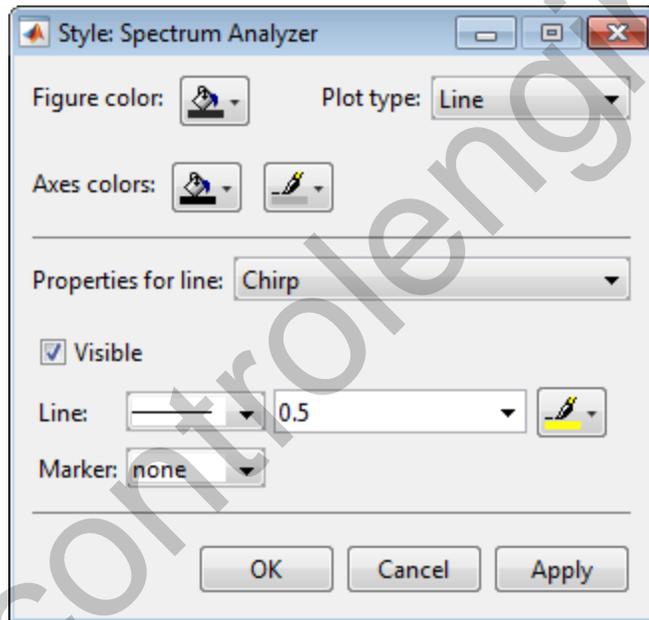

Set the signal power for the minimum color value of the spectrogram. Tunable.

**Color-limits (Maximum)**

Set the signal power for the maximum color value of the spectrogram. Tunable.

**Style Dialog Box**

In the **Style** dialog box, you can customize the style of spectrum display. This dialog box is not available for the spectrogram view. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View > Style** to open this dialog box.

**Properties**

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

### Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

### Plot type

Specify whether to display a **Line** or **Stem** plot.

### Axes colors

Specify the color that you want to apply to the background of the axes.

### Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

### Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

### Line

Specify the line style, line width, and line color for the selected channel.

### Marker

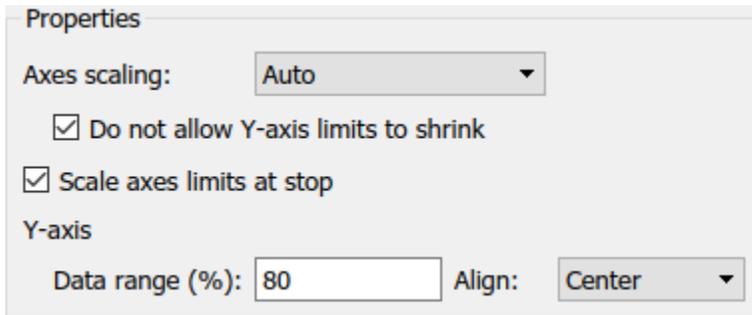

Specify marks for the selected channel to show at its data points. This parameter is similar to the **Marker** property for plot objects. You can choose any of the marker symbols from the dropdown.

## Tools — Axes Scaling Properties

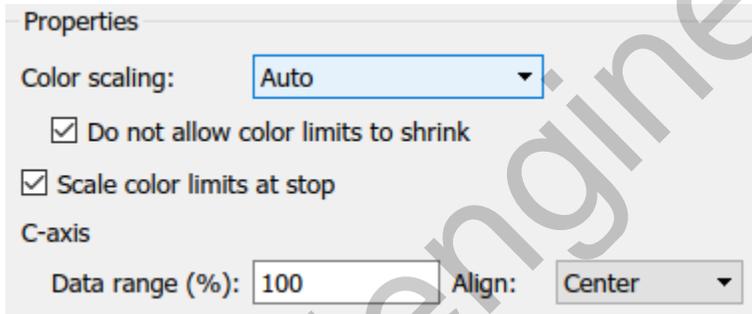

The **Tools — Axes Scaling Properties** dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes and color of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools > Scaling Properties** to open this dialog box.

### Properties

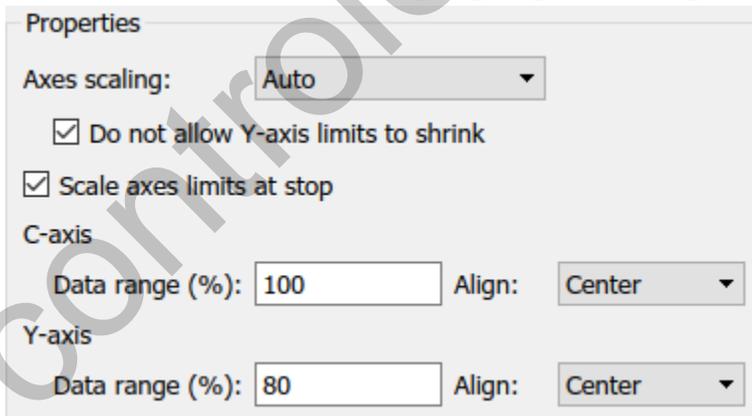

For the spectrum view, the **Tools—Axes Scaling Properties** dialog box appears as:

For spectrogram view, the Tools—Axes Scaling Properties dialog box appears as:

For dual view, the Tools—Axes Scaling Properties dialog box appears as:

---

**Note:** The X-axis scaling options only apply when using CCDF measurements.

---

## Axes scaling/Color scaling

Specify when the scope automatically scales the axes. If the spectrogram is displayed, specify when the scope automatically scales the color. You can select one of the following options:

- **Manual** — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools > Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- **Auto** — When you select this option, the scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink**.
- **After N Updates** — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this parameter is set to **Auto**, and the scope does not shrink the y-axis limits when scaling the axes or color. Tunable.

### Do not allow Y-axis limits to shrink / Do not allow color limits to shrink

When you select this property, the y-axis are allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this property allows the color limits to grow during axis scaling. If you clear this check box, the y-axis or color limits can shrink during axes scaling operations.

This property appears only when you select **Auto** for the **Axis scaling** or **Color scaling** property. When you set the **Axes scaling** or **Color scaling** property to **Manual** or **After N Updates**, the y-axis or color limits can shrink. Tunable.

### Number of updates

Specify as a positive integer the number of updates after which to scale the axes. If the spectrogram is displayed, this property specifies the number of updates after which to scale the color. This property appears only when you select **After N Updates** for the **Axes scaling** or **Color scaling** property. Tunable.

### Scale axes limits at stop/Scale color limits at stop

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

### Y-axis Data range (%) / Color-limits Data range

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this property to 100, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to 30, the scope increases the *y*-axis range or color such that your data uses only 30% of the *y*-axis range or color. Tunable.

### Y-axis Align / Color-limits Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the *y*-axis when it scales the color. You can select **Top**, **Center**, or **Bottom**. Tunable.

### Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to **Auto**, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable.

### X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to 100, the scope scales the *x*-axis limits such that your data uses the entire *x*-axis range. If you then set this property to 30, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable.

## X-axis Align

Specify how the scope aligns your data along the  $x$ -axis: **Left**, **Center**, or **Right**. This property appears only when you select the **Scale X-axis limits** check box. Tunable.

## Algorithms

Spectrum Analyzer uses the **RBW** or the **Window Length** setting in the **Spectrum Settings** panel to determine the data window length. The value of the **FrequencyResolutionMethod** property determines whether **RBW** or window length is used. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

- 1 Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth,  $RBW$ , by the following equation or to the window length, by the equation shown in step 1b.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth,  $NENBW$ , is a factor that depends on the windowing method. Spectrum Analyzer shows  $NENBW$  in the **Window Options** pane of the **Spectrum Settings** panel. Overlap percentage,  $O_p$ , is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel.  $F_s$  is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

- a When in **RBW** mode, the window length required to compute one spectral update,  $N_{window}$ , is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **WindowLength** mode, the window length is used as specified.

- b** The number of input samples required to compute one spectral update,  $N_{samples}$ , is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

$O_p$	$N_{samples}$
0%	100
50%	50
80%	20

- c** The normalized effective noise bandwidth,  $NENBW$ , is a window parameter determined by the window length,  $N_{window}$ , and the type of window used. If  $w(n)$  denotes the vector of  $N_{window}$  window coefficients, then  $NENBW$  is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[ \sum_{n=1}^{N_{window}} w(n) \right]^2}$$

- d** When in RBW mode, you can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

$$\frac{span}{RBW} > 2$$

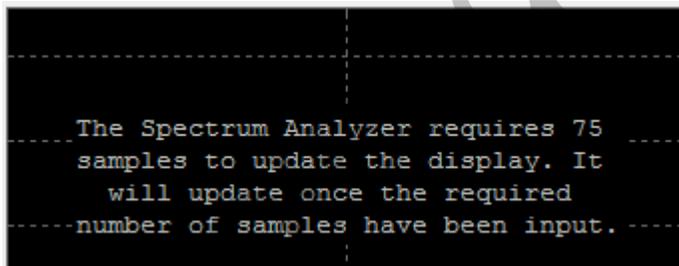

By default, the **RBW** parameter on the **Main options** pane is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to **Auto**, it is calculated by the following

$$\text{equation. } RBW_{auto} = \frac{span}{1024}$$

- e When in window length mode, you specify  $N_{window}$  and the resulting RBW is

$$\frac{NENBW * Fs}{N_{window}}$$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.

Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the Spectrum Scope block computed a spectral update using the number of samples in each frame.

- 2 Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see `periodogram` in the Signal Processing Toolbox documentation.

*Power Spectral Density* — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation,  $x[n]$  is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, each window denoted as  $x^{(p)}[n]$ , and computes their periodograms. Spectrum Analyzer displays a running average of the  $P$  most current periodograms.

*Power Spectrum* — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[ \sum_{n=1}^{N_{window}} w[n] \right]^2}$$

---

**Note:** The number of FFT points ( $N_{fft}$ ) is independent of the window length ( $N_{window}$ ). You can set them to different values provided that  $N_{fft}$  is greater than or equal to  $N_{window}$ .

---

The *Occupied BW* is calculated as follows.

- Calculate the total power in the measured frequency range.
- Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this sum is  $\frac{100 - \text{Occupied BW } \%}{2}$  of the total power.

- Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until it reaches  $\frac{100 - \text{Occupied BW \%}}{2}$  of the total power.
- The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- The frequency halfway between the lower and upper frequency values is the center frequency.

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it clears all monotonically decreasing values (that is, it treats all of these values as if they belong to the peak). Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared ( $W_0$ ) is recorded.
- 2 The fundamental power ( $P_1$ ) is determined from the remaining maximum value of the displayed spectrum. A local estimate ( $Fe_1$ ) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content ( $W_1$ ) is recorded. Then, the power associated from the fundamental is removed as in step 1.
- 3 The power and width of the second, and higher order harmonics ( $P_2, W_2, P_3, W_3$ , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate ( $Fe_1$ ). Any spectral content that decreases in a monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ( $P_{remaining}$ ) peak value ( $P_{maxspur}$ ), and its median value ( $P_{estnoise}$ ).
- 5 The sum of all the removed bandwidth is computed as  $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$ .

The sum of powers of the second and higher order harmonics are computed as

$$P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n.$$

- 6 The sum of the noise power is then estimated as  $P_{noise} = (P_{remaining} * dF + P_{estnoise} * W_{sum}) / RBW$ , where  $dF$  is the absolute difference between frequency bins, and  $RBW$  is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left( \frac{P_{harmonic}}{P_1} \right)$$

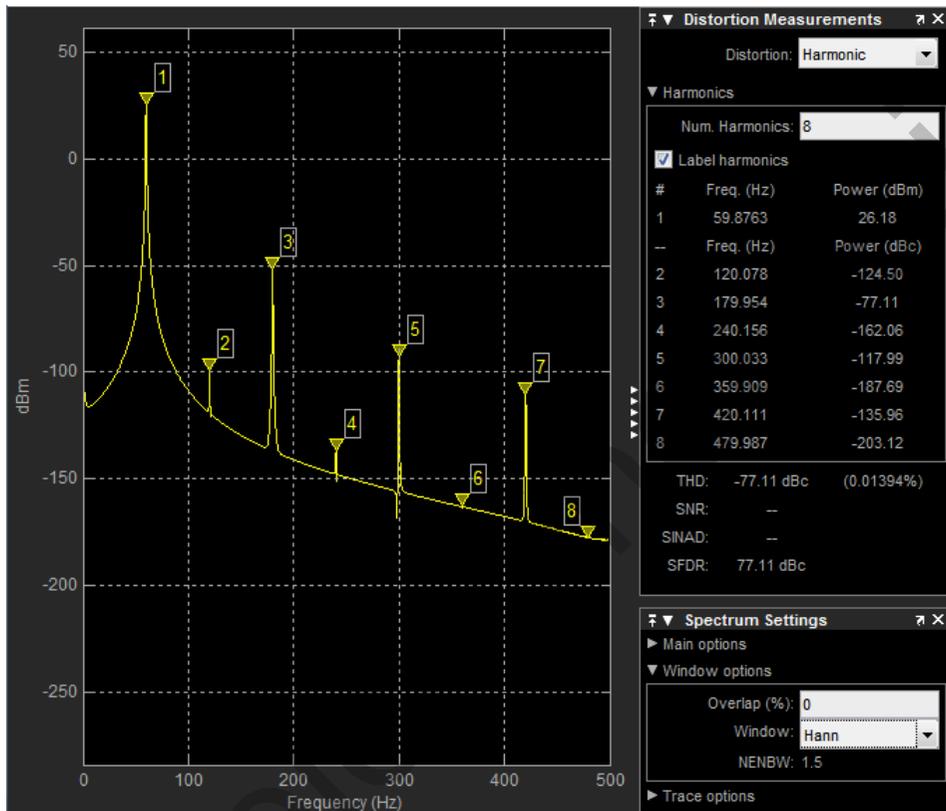

$$SINAD = 10 \cdot \log_{10} \left( \frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left( \frac{P_1}{P_{noise}} \right)$$

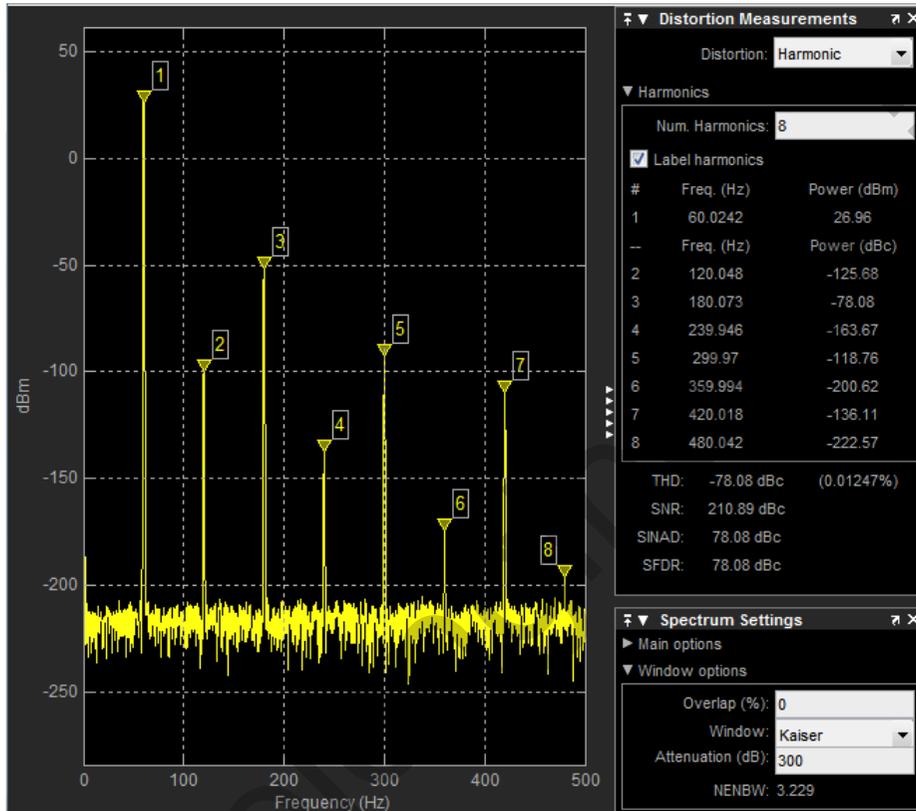

$$SFDR = 10 \cdot \log_{10} \left( \frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

The following considerations apply to *Distortion Measurements*.

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default HANN window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. Consider using a Kaiser window with a high attenuation (up to 330dB) to minimize spectral leakage if your application can tolerate the increased equivalent noise bandwidth (ENBW) of the Kaiser window.

- The DC component is ignored.
- After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- $N$ th order intermodulation products occur at

$$A * F1 + B * F2$$

where  $F1$  and  $F2$  are the sinusoid input frequencies and  $|A| + |B| = N$ .  $A$  and  $B$  are integer values.

- For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where  $P$  is power in decibels of the measured power referenced to one milliwatt (dBm).:
  - $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
  - $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
  - $TOI = + (TOI_{lower} + TOI_{upper})/2$

## Differences from Spectrum Scope Block

All Simulink models containing Spectrum Scope blocks load with Spectrum Analyzer blocks in R2013a or later. Several options that were available on the Parameters dialog box of the Spectrum Scope block are no longer available or have changed. The parameters of Spectrum Scope map to Spectrum Analyzer parameters in the following manner.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	<b>Buffer input</b> check box	R2013a Spectrum Analyzer does not require that input signals are buffered. Spectrum Analyzer determines the number of samples needed using the value of the <b>RBW</b> parameter. Regardless of whether the input is a frame-based or sample-based signal, Spectrum Analyzer calculates the spectrum once it has acquired the requisite number of samples.	For Spectrum Scope blocks in R2012b or earlier models, the equivalent R2013a Spectrum Analyzer <b>RBW</b> value is given by the equation: $RBW = \frac{NENBW \times F_s}{N_{window}}$ In the preceding equation, $NENBW$ is the window constant calculated for a window length of 1000, $F_s$ is the sample rate of the block,

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
			and $N_{window}$ is the buffer length. If the input signal to the R2012b Spectrum Scope block was frame-based and the <b>Buffer input</b> check box was cleared, then the R2013a Spectrum Analyzer computes the <b>RBW</b> value with $N_{window}$ set to the frame size of the input signal.
Scope Properties	<b>Buffer size</b> parameter	R2013a Spectrum Analyzer uses the <b>RBW</b> parameter to determine the requisite number of samples to calculate the spectrum, instead of using the buffer size or frame length.	For Spectrum Scope blocks in R2012b or earlier models, if the input signal was frame-based and the <b>Buffer input</b> check box was selected, then the R2013a Spectrum Analyzer computes the <b>RBW</b> value with $N_{window}$ set to the value of the <b>Buffer size</b> parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	<b>Buffer Overlap</b> parameter	R2013a Spectrum Analyzer has an <b>Overlap</b> % parameter that is directly related to buffer overlap.	R2013a Spectrum Analyzer will compute its <b>Overlap</b> % using the equation: $O_p = O_l / N_{window} \times 100$ <p>In the preceding equation, <math>O_p</math> is <b>Overlap</b> % parameter value, <math>O_l</math> is the R2012b Spectrum Scope <b>Buffer overlap</b> parameter value, and <math>N_{window}</math> is the buffer length.</p>
Scope Properties	<b>Treat Mx1 and unoriented sample-based signals as</b>	R2013a Spectrum Analyzer defaults to treating Mx1 and unoriented sample-based signals as one channel.	Spectrum Scope blocks in R2012b or earlier models with <b>Treat Mx1 and unoriented sample-based signals as</b> set to M Channels will have the Spectrum Analyzer property <code>TreatMby1SignalAsOneChannel</code> set to <code>false</code> . This property is available only via the Scope Configuration object.
Scope Properties	<b>Window</b> parameter	R2013a Spectrum Analyzer does not have the <b>Bartlett</b> , <b>Blackman</b> , <b>Triang</b> , or <b>Hanning</b> settings.	Spectrum Scope blocks in R2012b or earlier models with a window parameter set to any of these values will have their <b>Window</b> parameter set to <b>Hann</b> in the R2013a Spectrum Analyzer.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	<b>Window Sampling</b> parameter	R2013a Spectrum Analyzer does not have a <b>Periodic</b> option. All window sampling is now symmetric in the R2013a Spectrum Analyzer.	n/a
Display Properties	<b>Persistence</b> check box — this setting would execute the equivalent of the MATLAB hold on command, adding another line for each spectrum computation on the display.	This option is not available in the R2013a Spectrum Analyzer, which has replaced this feature with the trace options, <b>Normal Trace</b> , <b>Max Hold Trace</b> , and <b>Min Hold Trace</b> .	Spectrum Scope blocks in R2012b or earlier models with persistence enabled will have their <b>Max Hold Trace</b> check box selected in the R2013a Spectrum Analyzer.
Display Properties	<b>Compact Display</b> check box	There is no equivalent capability in the R2013a Spectrum Analyzer.	n/a
Axis Properties	<b>Inherit Sample time from input</b> check box	R2013a Spectrum Analyzer always uses the sample time of the input signal.	n/a

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Axis Properties	<b>Frequency display limits</b> parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the <b>Full Span</b> , <b>FStart (Hz)</b> , and <b>FStop (Hz)</b> parameters.	If this parameter was set to: <ul style="list-style-type: none"> <li>• <b>Auto</b> — R2013a Spectrum Analyzer selects the <b>Full Span</b> check box on the Spectrum Settings panel, Main options pane.</li> <li>• <b>User-defined</b> — R2013a Spectrum Analyzer clears the <b>Full Span</b> check box on the Spectrum Settings panel Main options pane.</li> </ul>
Axis Properties	<b>Minimum frequency (Hz)</b> parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the <b>Full Span</b> , <b>FStart (Hz)</b> , and <b>FStop (Hz)</b> parameters.	If the <b>User-defined</b> parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer <b>FStart (Hz)</b> parameter.
Axis Properties	<b>Maximum frequency (Hz)</b> parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the <b>Full Span</b> , <b>FStart (Hz)</b> , and <b>FStop (Hz)</b> parameters.	If the <b>User-defined</b> parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer <b>FStop (Hz)</b> parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Line Properties	<b>Line visibilities</b> , <b>Line styles</b> , <b>Line markers</b> , and <b>Line colors</b> parameters	There are no equivalent capabilities in the R2013a Spectrum Analyzer.	Once the simulation has started, you can modify the line styles, markers, and colors using the Style dialog box.

The R2012b Spectrum Scope allowed you to retain the axes limits over multiple simulations by selecting **Axes > Save Axes Settings**. There is no equivalent capability in the R2013a Spectrum Analyzer. However, you can automatically scale the axes to a specified range using the Tools — Axes Scaling Properties dialog box.

## Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> </ul>

## Supported Simulation Modes

You can use the scope block in models running the following supported simulation modes.

Mode	Supported	Notes and Limitations
Normal	Yes	

Mode	Supported	Notes and Limitations
Accelerator	Yes	
Rapid Accelerator	Yes	You can use Rapid Accelerator mode as a method to increase the execution speed of your Simulink model. Rapid Accelerator mode creates an executable that includes the solver and model methods. This executable resides outside MATLAB and Simulink. Rapid Accelerator mode uses External mode to communicate with Simulink. For more information about Rapid Accelerator mode, see “Acceleration”.
PIL	No	
SIL	No	
External	Yes	<p>You can use External mode to tune block parameters in real time and view block outputs in many types of blocks and subsystems. External mode establishes communication between a host system, where the Simulink environment resides, and a target system, where the executable runs after code generation and the build process. For more information about External mode, see “Set Up and Use Host/Target Communication Channel” (Simulink Coder).</p> <p>The scope does not support data archiving. See “Set External Mode Data Archiving Parameters” (Simulink Desktop Real-Time).</p>

For more information about these modes, see “How Acceleration Modes Work”.

## Slider Switch

Set on/off values to tune parameters or variables

## Library

Dashboard

## Description

The Slider Switch block enables you to control tunable parameters and variables in your model during simulation. The block has two states that can be set to two different values.

To control a tunable parameter or variable using the Slider Switch block, double-click the Slider Switch block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

## Limitations

The Slider Switch block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b>

Limitation	Workaround
	table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### States

Switch values and labels.

### Settings

**Default Labels:** Off and On

**Default Values:** 0 and 1

By default, the **Off** state label corresponds to the set value of 0, and the **On** state label corresponds to the set value of 1.

The state labels appear on the outside of the switch. You can change the state labels to another character vector. You can change the state values to any real value that is between negative `realmax` and positive `realmax`.

## Label

Position of the block label or instructional text if the block is not connected.

## Settings

**Default:** Top

Top

Show the label at the top of the block.

Bottom

Show the label at the bottom of the block.

Hide

Do not show the label or instructional text when the block is not connected.

## Examples

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

**Introduced in R2015a**

# Sqrt, Signed Sqrt, Reciprocal Sqrt

Calculate square root, signed square root, or reciprocal of square root

## Library

Math Operations

## Description

You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
sqrt	Square root of the input	$u^{0.5}$	sqrt
signedSqrt	Square root of the absolute value of the input, multiplied by the sign of the input	$\text{sign}(u) *  u ^{0.5}$	—
rSqrt	Reciprocal of the square root of the input	$u^{-0.5}$	—

The block output is the result of applying the function to the input. Each function supports:

- Scalar operations
- Element-wise vector and matrix operations

## Data Type Support

The block accepts input signals of the following data types:

Function	Input Data Types	Restrictions
sqrt	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed point</li> </ul>	None
signedSqrt	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed point</li> </ul>	When the input is an integer or fixed-point type, the output must be floating point.
rSqrt	<ul style="list-style-type: none"> <li>Floating point</li> <li>Built-in integer</li> <li>Fixed point</li> </ul>	None

The block accepts real and complex inputs of the following types:

Function	Types of Real Inputs	Types of Complex Inputs
sqrt	Any, except for fixed-point inputs that are negative or have nontrivial slope and nonzero bias	Any, except for fixed-point inputs
signedSqrt		None
rSqrt		None

The block output:

- Uses the data type that you specify for **Output data type**
- Is real or complex, depending on your selection for **Output signal type**

## Parameters

### Function

Specify the mathematical function. The block icon changes to match the function you select.

Function	Block Icon
sqrt	

Function	Block Icon
signedSqrt	
rSqrt	

### Output signal type

Specify the output signal type of the block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
sqrt	real	real for nonnegative inputs NaN for negative inputs	real for nonnegative inputs NaN for negative inputs	complex
	complex	complex	error	complex
signedSqrt	real	real	real	complex
	complex	error	error	error
rSqrt	real	real	real	error
	complex	error	error	error

### Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

**Note:** The parameters in the **Algorithm** pane are available only when you set **Function** to rSqrt on the **Main** pane.

### Method

Specify the method for computing the reciprocal of a square root.

Method	Data Types Supported	When to Use This Method
Exact	Floating point	You do not want an approximation.
	If you use a fixed-point or built-in integer type, an upcast to a floating-point type occurs.	<b>Note:</b> The input or output must be floating point.
Newton-Raphson	Floating-point, fixed-point, and built-in integer types	You want a fast, approximate calculation.

The `Exact` method provides results that are consistent with MATLAB computations.

---

**Note:** The algorithms for `sqrt` and `signedSqrt` are always of `Exact` type, no matter what selection appears on the block dialog box.

---

### Number of iterations

Specify the number of iterations to perform the Newton-Raphson algorithm. The default value is 3.

This parameter is not available when you select `Exact` for **Method**.

---

**Note:** If you enter 0, the block output is the initial guess of the Newton-Raphson algorithm.

---

### Intermediate results data type

Specify the data type for intermediate results (available only when you set **Function** to `sqrt` or `rSqrt` on the **Main** pane). You can set the data type to:

- A rule that inherits a data type, for example, `Inherit:Inherit` via `internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Follow these guidelines on setting an intermediate data type explicitly for the square root function, `sqrt`:

Input and Output Data Types	Intermediate Data Type
Input or output is double.	Use double.
Input or output is single, and any non-single data type is <i>not</i> double.	Use single or double.
Input and output are fixed point.	Use fixed point.

Follow these guidelines on setting an intermediate data type explicitly for the reciprocal square root function, `rSqrt`:

Input and Output Data Types	Intermediate Data Type
Input is double and output is not single.	Use double.
Input is not single and output is double.	Use double.
Input and output are fixed point.	Use fixed point.

**Caution:** Do not set **Intermediate results data type** to `Inherit:Inherit` from output when:

- You select `Newton-Raphson` to compute the reciprocal of a square root.
- The input data type is floating point.
- The output data type is fixed point.

Under these conditions, selecting `Inherit:Inherit` from output yields suboptimal performance and produces an error.

To avoid this error, convert the input signal from a floating-point to fixed-point data type. For example, insert a `Data Type Conversion` block in front of the `Sqrt` block to perform the conversion.

### Output data type

Specify the output data type. You can set the data type to:

- A rule that inherits a data type, for example, `Inherit:Inherit` via `back propagation`
- The name of a built-in data type, for example, `single`

- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the Simulink User's Guide for more information.

### Output minimum

Specify the minimum value that the block can output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Output maximum

Specify the maximum value that the block can output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

### Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this

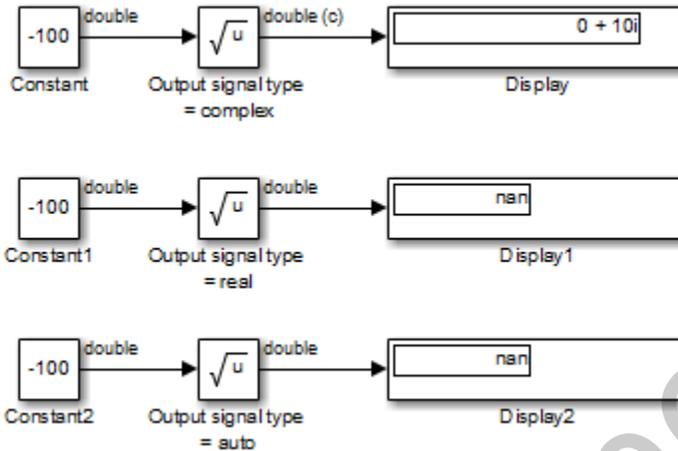

Action	Reasons for Taking This Action	What Happens for Overflows	Example
			maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	<p>The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code>, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code>, is -126.</p>

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Examples

### sqrt Function

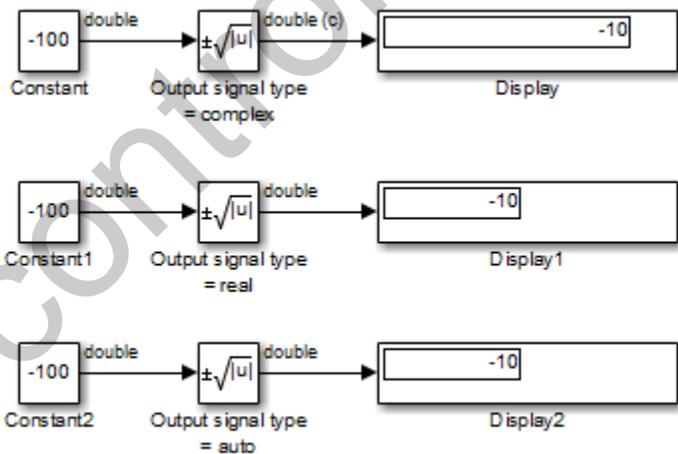

Suppose that you have the following model:

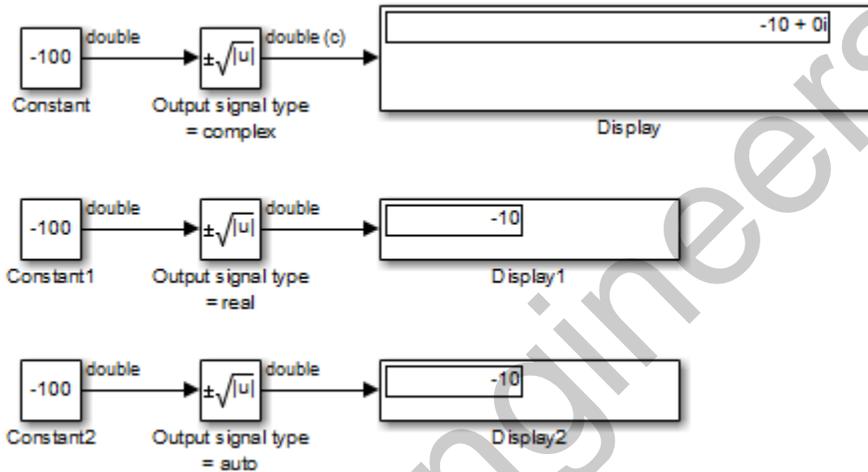

When the input to the Sqrt block is negative and the **Output signal type** is **auto** or **real**, the sqrt function outputs NaN. However, setting **Output signal type** to **complex** produces the correct answer.

### signedSqrt Function

Suppose that you have the following model:

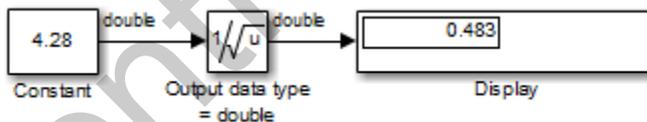

When the input to the Sqrt block is negative, the block output is the same for any **Output signal type** setting. If you change the first Display block format from **short** to **decimal (Stored Integer)**, you see the value of the imaginary part for the complex output.

### rSqrt Function with Floating-Point Inputs

Suppose that you have the following model:

In the Sqrt block dialog box, assume that the following parameter settings apply:

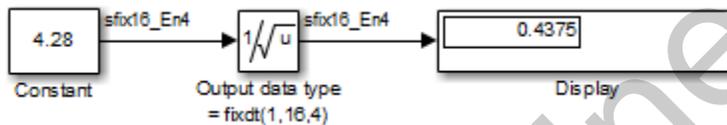

Parameter	Setting
Method	Newton-Raphson
Number of iterations	1

Parameter	Setting
Intermediate results data type	Inherit:Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0004 of the final value (0.4834).

## rSqrt Function with Fixed-Point Inputs

Suppose that you have the following model:

In the Sqrt block dialog box, assume that the following parameter settings apply:

Parameter	Setting
Method	Newton-Raphson
Number of iterations	1
Intermediate results data type	Inherit:Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0459 of the final value (0.4834).

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Code Generation	Yes

# Squeeze

Remove singleton dimensions from multidimensional signal

## Library

Math Operations

## Description

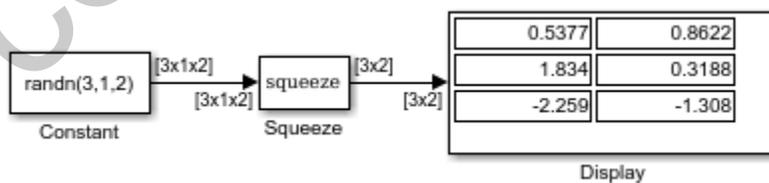

The Squeeze block removes singleton dimensions from its multidimensional input signal. A singleton dimension is any dimension whose size is one. The Squeeze block operates only on signals whose number of dimensions is greater than two. Scalar, one-dimensional (vector), and two-dimensional (matrix) signals pass through the Squeeze block unchanged.

## Data Type Support

The Squeeze block accepts input signals of any dimension and of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples

In the following model, the Squeeze block converts a multidimensional array of size 3-by-1-by-2 into a 3-by-2 signal:

Because the Constant block supplies a signal with random values to the Squeeze block, the values in the Display block vary from simulation to simulation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes

## State Control

Specify synchronous reset and enable behavior for blocks with state

Synchronous

## Library

HDL Coder / HDL Subsystems

## Description

The State Control block in **Synchronous** mode improves the HDL simulation behavior of blocks with state, or blocks that have reset or enable ports. The simulation behavior in **Classic** mode is the same as when you do not add the State Control block inside the subsystem.

When use the **Synchronous** mode of the block, the Simulink simulation behavior closely matches that of the digital hardware.

If you have HDL Coder installed, you can generate cleaner HDL code with the **Synchronous** mode of the State Control block. For more information, see State Control.

## Parameters

### State control

Specify whether to use synchronous or classic semantics. The default is Synchronous.

## Limitations

The following limitations apply to using the State Control block in Simulink. For information about this block in HDL Coder, see State Control in the HDL Coder documentation.

## Block-Level Limitations

- For synchronous semantics in S-function blocks, set the method `ssSetStateSemanticsClassicAndSynchronous` to `true`.
- Discrete-Time Integrator blocks with a reset port do not support synchronous semantics.
- All action subsystems connected to **If** and **Switch Case** blocks must have the same semantics, either classic or synchronous.
- The following blocks are not allowed in synchronous mode:
  - Continuous time blocks and blocks with continuous rate
  - Simulink blocks with **Input processing** set to **Columns** as channels (frame based), where this parameter applies.
  - Trigger block
  - From Workspace block
  - The set of unit delay blocks in the **Additional Math & Discrete > Additional Discrete** sublibrary in Simulink, such as the Unit Delay Resettable and Unit Delay External IC blocks

## Subsystem-level Limitations

- Conditional subsystems using classic semantics cannot have subsystems with synchronous semantics inside them.
- Conditional subsystems must be single rate when you use the State Control block in synchronous mode.
- Synchronous Enabled Subsystem cannot contain reset subsystems or a reset parameter port. For example, you cannot have a **Delay** block with an external reset port inside the subsystem.
- These blocks are not supported in synchronous mode:
  - For Iterator Subsystem
  - While Iterator Subsystem
  - Function-Call Subsystem
  - Triggered Subsystem

## Model-Level Limitations

- Variable-size signals are not supported with synchronous semantics.
- Synchronous semantics do not propagate across model boundaries. If your parent model has synchronous semantics, any referenced model must have synchronous semantics explicitly specified. At the root level of each referenced model, add a State Control block with the **State control** parameter set to **Synchronous**.

## State Reader

Read a block state

**Library:** Signal Routing

### Description

The State Reader block reads the current state of a supported state owner block.

Add a State Reader block to your model from the Simulink Library Browser.

State Reader blocks can read state from these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- S-Function (with one data type work vector declared as a discrete-state vector )

### Ports

#### Output

**Out** — State value

scalar | vector

State value read from a state owner block.

The dimension of the output is the dimension of the full state vector. Refer to the **Initial conditions** parameter for specific blocks. For example, for a Delay block with a **Delay length** of N, the State Reader block returns a state vector of length [ 1xN].

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

## Parameters

### State owner block — Show the state owner block

none (default)

Show the state owner block whose state this block is reading. To change the state owner block, select a block from the **State Owner Selector Tree**.

## See Also

### See Also

Event Listener | Initialize Function | Reset Function | State Writer | Terminate Function

### Topics

“Create Model to Initialize, Reset, and Terminate State”

## State Writer

Write to a block state

**Library:** Signal Routing

### Description

The State Writer block sets the state of a supported state owner block.

Add a State Writer block to your model from the Simulink Library Browser.

State Writer blocks can write state to these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- S-Function (with one data type work vector declared as a discrete-state vector )

### Ports

#### Input

**In — State value**

scalar | vector

State value written to a state owner block.

When writing to a state owner block with an input scalar, the scalar value is expanded to match the dimension of the state. All elements of the state are set to the same value.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

## Parameters

### State owner block — Show the state owner block

none (default)

Show the state owner block whose state this block is writing. To change the state owner block, select a block from the **State Owner Selector Tree**.

## See Also

### See Also

Event Listener | Initialize Function | Reset Function | State Reader | Terminate Function

### Topics

“Create Model to Initialize, Reset, and Terminate State”

## State-Space

Implement linear state-space system

$$\begin{cases} \dot{x} = Ax + Bu \\ y = Cx + Du \end{cases}$$

## Library

Continuous

## Description

The State-Space block implements a system whose behavior you define as

$$\begin{aligned} \dot{x} &= Ax + Bu \\ y &= Cx + Du \\ x|_{t=t_0} &= x_0, \end{aligned}$$

where  $x$  is the state vector,  $u$  is the input vector,  $y$  is the output vector and  $x_0$  is the initial condition of the state vector. The matrix coefficients must have these characteristics:

- $A$  must be an  $n$ -by- $n$  matrix, where  $n$  is the number of states.
- $B$  must be an  $n$ -by- $m$  matrix, where  $m$  is the number of inputs.
- $C$  must be an  $r$ -by- $n$  matrix, where  $r$  is the number of outputs.
- $D$  must be an  $r$ -by- $m$  matrix.

	n	m
n	A	B
r	C	D

In general, the block has one input port and one output port. The number of rows in  $C$  or  $D$  matrix is the same as the width of the output port. The number of columns in the  $B$  or  $D$  matrix are the same as the width of the input port. If you want to model

an autonomous linear system with no inputs, set the B and D matrices to empty. In this case, the block acts as a source block with no input port and one output port, and implements the following system:

$$\begin{aligned} \dot{x} &= Ax \\ y &= Cx \\ x|_{t=t_0} &= x_0. \end{aligned}$$

Simulink software converts a matrix containing zeros to a sparse matrix for efficient multiplication.

## Data Type Support

A State-Space block accepts and outputs real signals of type double.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### A

Specify the n-by-n matrix coefficient, where n is the number of states.

### Settings

Default: 1

### Command-Line Information

Parameter: A

Type: matrix

Value: ' 1 '

Default: ' 1 '

## B

Specify the n-by-m matrix coefficient, where n is the number of states and m is the number of inputs.

### Settings

Default: 1

### Command-Line Information

Parameter: B

Type: matrix

Value: '1'

Default: '1'

Controlengineers.ir

## C

Specify the r-by-n matrix coefficient, where r is the number of outputs and n is the number of states.

### Settings

Default: 1

### Command-Line Information

Parameter: C

Type: matrix

Value: '1'

Default: '1'

Controlengineers.ir

## D

Specify the r-by-m matrix coefficient, where r is the number of outputs and m is the number of inputs.

### Settings

**Default:** 1

### Command-Line Information

**Parameter:** D

**Type:** matrix

**Value:** '1'

**Default:** '1'

Controlengineers.ir

## Initial conditions

Specify the initial state vector.

### Settings

**Default:** 0

The initial conditions of this block cannot be `inf` or `NaN`.

### Command-Line Information

**Parameter:** `X0`

**Type:** vector

**Value:** '0'

**Default:** '0'

Controlengineers.ir

## Absolute tolerance

Specify the absolute tolerance for computing block states.

### Settings

**Default:** auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

### Command-Line Information

**Parameter:** AbsoluteTolerance

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

## State Name (e.g., 'position')

Assign a unique name to each state.

### Settings

**Default:** ' '

If this field is blank, no name assignment occurs.

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

### Command-Line Information

**Parameter:** ContinuousStateAttributes

**Type:** character vector

**Value:** ' ' | user-defined

**Default:** ' '

## Examples

The following Simulink examples show how to use the State-Space block:

- sldemo\_dbldcart1
- aero\_vibrati

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Only if $D \neq 0$
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Discrete State-Space

Transfer Fcn

Introduced before R2006a

## Step

Generate step function

## Library

Sources

## Description

The Step block provides a step between two definable levels at a specified time. If the simulation time is less than the **Step time** parameter value, the block's output is the **Initial value** parameter value. For simulation time greater than or equal to the **Step time**, the output is the **Final value** parameter value.

The numeric block parameters must be of the same dimensions after scalar expansion. If the **Interpret vector parameters as 1-D** option is off, the block outputs a signal of the same dimensions and dimensionality as the parameters. If the **Interpret vector parameters as 1-D** option is on and the numeric parameters are row or column vectors (that is, single row or column 2-D arrays), the block outputs a vector (1-D array) signal. Otherwise, the block outputs a signal of the same dimensionality and dimensions as the parameters.

## Data Type Support

The Step block outputs real signals of type double.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Step time

Specify the time, in seconds, when the output jumps from the **Initial value** parameter to the **Final value** parameter. The default is 1 second.

### Initial value

Specify the block output until the simulation time reaches the **Step time** parameter. The default is 0.

### Final value

Specify the block output when the simulation time reaches and exceeds the **Step time** parameter. The default is 1.

### Sample time

Specify the sample rate of step. See “Specify Sample Time” in the online documentation for more information.

### Interpret vector parameters as 1-D

If selected, column or row matrix values for the Step block's numeric parameters result in a vector output signal; otherwise, the block outputs a signal of the same dimensionality as the parameters. If this option is not selected, the block always outputs a signal of the same dimensionality as the block's numeric parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

## Examples

The following Simulink examples show how to use the Step block:

- sldemo\_doublebounce
- sldemo\_enginewc

## Characteristics

Data Types	Double
------------	--------

Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled.
Code Generation	Yes

## See Also

Ramp

Introduced before R2006a

Controlengineers.ir

# Stop Simulation

Stop simulation when input is nonzero

## Library

Sinks

## Description

The Stop Simulation block stops the simulation when the input is nonzero. The simulation completes the current time step before terminating. If the block input is a vector, any nonzero vector element causes the simulation to stop.

When you use the Stop Simulation block in a For Iterator subsystem, the stop action occurs after execution of *all* the iterations in the subsystem during a time step. The stop action does not interrupt execution until the start of the next time step.

You cannot use the Stop Simulation block to pause the simulation. To create a block that pauses the simulation, see “Pause Simulation Using Assertion Blocks” in the Simulink documentation.

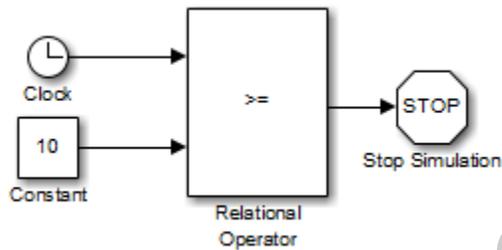

## Data Type Support

The Stop Simulation block accepts real signals of type `double` or `Boolean`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples

### Usage with the Relational Operator Block

You can use the Stop Simulation block with the Relational Operator block to control when a simulation stops. For example, the following model stops simulation when the simulation time reaches 10.

### Usage with the Integrator Block

You can use the Stop Simulation block with the Integrator block to control when a simulation stops. For example, the `sldemo_absbrake` model stops simulation when the saturation port of the Integrator block outputs a value of 1 or  $-1$ .

# Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem

Represent system within another system

## Library

Ports & Subsystems

## Description

A subsystem block contains a subset of blocks or code within an overall model or system. The subsystem block can represent a virtual subsystem or a nonvirtual subsystem.

In nonvirtual subsystems, you can control when the contents of the subsystem are evaluated. Nonvirtual subsystems are executed as a single unit (atomic execution). You can create conditionally executed nonvirtual subsystems that execute only when a transition occurs on a triggering, function-call, action, or enabling input (see “Conditionally Executed Subsystems”).

A subsystem is virtual if the block is neither conditionally executed nor atomic. Virtual subsystems do not have checksums.

---

**Tip:** To determine if a subsystem is virtual, use the `get_param` function for the Boolean block parameter `IsSubsystemVirtual`.

---

An **Atomic Subsystem** block is a subsystem block in which **Treat as atomic unit** is selected by default.

A **CodeReuse Subsystem** block is a subsystem block in which **Treat as atomic unit** is selected and **Function packaging** is set to `Reusable function`, specifying the function code generation format for the subsystem. (see “Function packaging” on page 1-1784 for details).

To create a subsystem, do one of the following:

- Copy a subsystem block from the Ports & Subsystems library into your model. Then add blocks to the subsystem by opening the subsystem block and copying blocks into it.
- Select all blocks and lines that make up the subsystem, and select **Diagram > Subsystem & Model Reference > Create Subsystem from Selection**. Simulink replaces the blocks with a subsystem block, along with the necessary Inport and Outport blocks to reflect signals entering and leaving the subsystem.

The number of input ports drawn on the subsystem block's icon corresponds to the number of Inport blocks in the subsystem. Similarly, the number of output ports drawn on the block corresponds to the number of Outport blocks in the subsystem.

The subsystem block supports signal label propagation through subsystem Inport and Outport blocks.

See “Create a Subsystem” for more information.

## Data Type Support

See Inport for information on the data types accepted by a subsystem's input ports. See Outport for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

---

**Note:** Parameters on the Code Generation tab require a Simulink Coder or Embedded Coder license. For more information, see the parameter sections.

---

## Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

### Settings

**Default:** FromPortIcon

none

Does not display port labels on the subsystem block.

FromPortIcon

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

FromPortBlockName

Display the name of the corresponding port block on the subsystem block.

SignalName

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Read/Write permissions

Control user access to the contents of the subsystem.

### Settings

**Default:** ReadWrite

#### ReadWrite

Enables opening and modification of subsystem contents.

#### ReadOnly

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

#### NoReadOrWrite

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

### Settings

**Default:** ' '

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

### Settings

**Default:** All

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, Simulink.Signal objects).

ExplicitOnly

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

### Settings

**Default:** Off

On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

### Dependencies

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-1779.
- “Sample time (-1 for inherited)” on page 1-1782
- “Function packaging” on page 1-1784 (requires a Simulink Coder license)

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

### Settings

**Default:** On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Minimize algebraic loop occurrences

Try to eliminate any artificial algebraic loops that include the atomic subsystem

### Settings

**Default:** Off

On

Try to eliminate any artificial algebraic loops that include the atomic subsystem.

Off

Do not try to eliminate any artificial algebraic loops that include the atomic subsystem.

### Dependency

“Treat as atomic unit” on page 1-1777 enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Propagate execution context across subsystem boundary

Enable execution context propagation across the boundary of this subsystem.

### Settings

**Default:** Off

On

Enables execution context propagation across this subsystem's boundary.

Off

Does not enable execution context propagation across this subsystem's boundary.

### Dependency

Conditional execution of the subsystem enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Warn if function-call inputs are context-specific

Simulink displays a warning if it has to compute any of this function-call subsystem's inputs directly or indirectly during execution of a function-call.

### Settings

**Default:** Off

On

Simulink displays a warning if it has to compute any of this function-call subsystem's inputs directly or indirectly during execution of a function-call.

Off

Simulink does not display a warning if it has to compute any of this function-call subsystem's inputs directly or indirectly during execution of a function-call.

### Dependency

Use of a function-call subsystem enables this parameter.

The option is effective only when the **Context-dependent inputs** diagnostic on the **Diagnostics > Connectivity** pane of the Configuration Parameters dialog box is set to Use local settings.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time (-1 for inherited)

Specify whether all blocks in this subsystem must run at the same rate or can run at different rates.

### Settings

**Default:** -1

- -1

Specify the inherited sample time. Use this sample time if the blocks in the subsystem can run at different rates.

- [Ts 0]

Specify periodic sample time.

### Tips

- If the blocks in the subsystem can run at different rates, specify the subsystem's sample time as inherited (-1).
- If all blocks must run at the same rate, specify the sample time corresponding to this rate as the value of the subsystem's **Sample time** parameter.
- If any of the blocks in the subsystem specify a different sample time (other than -1 or `inf`), Simulink software displays an error message when you update or simulate the model. For example, suppose all the blocks in the subsystem must run 5 times a second. To ensure this, specify the sample time of the subsystem as 0.2. In this example, if any of the blocks in the subsystem specify a sample time other than 0.2, -1, or `inf`, Simulink software displays an error when you update or simulate the model.

### Dependency

“Treat as atomic unit” on page 1-1777 enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Variant control

Enter the variant activation condition or the variant control that contains the expression for variant activation.

The variant control can be a boolean condition expression or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, define control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

### Dependency

Adding a Subsystem block inside a Variant Subsystem block enables this parameter

### Command-Line Information

**Structure field:** Represented by the `variant.Name` field in the `Variants` parameter structure

**Type:** character vector

**Value:** Variant control associated with the variant

**Default:** ''

### See Also

- `Simulink.Variant`

## Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

### Settings

#### Default: Auto

##### Auto

Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

##### Inline

Simulink Coder software inlines the subsystem unconditionally.

##### Nonreusable function

Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments depending on the “Function interface” on page 1-1793 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-1788 and “File name (no extension)” on page 1-1791. These functions are not reentrant.

##### Reusable function

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

### Tips

- When you want multiple instances of a subsystem to be represented as one reusable function, you can designate each one of them as **Auto** or as **Reusable function**. It is best to use one or the other, as using both creates two reusable functions, one for each designation. The outcomes of these choices differ only when reuse is not possible. Selecting **Auto** does not allow control of the function or file name for the subsystem code.
- The **Reusable function** and **Auto** options both try to determine if multiple instances of a subsystem exist and if the code can be reused. The difference between the options' behavior is that when reuse is not possible:

- **Auto** yields inlined code, or if circumstances prohibit inlining, separate functions for each subsystem instance.
- **Reusable function** yields a separate function with arguments for each subsystem instance in the model.
- If you select **Reusable function** while your generated code is under source control, set **File name options** to **Use subsystem name**, **Use function name**, or **User specified**. Otherwise, the names of your code files change whenever you modify your model, which prevents source control on your files.

### Dependencies

- This parameter requires a Simulink Coder license.
- “Treat as atomic unit” on page 1-1777 enables this parameter.
- Setting this parameter to **Nonreusable function** or **Reusable function** enables the following parameters:
  - “Function name options” on page 1-1786
  - “File name options” on page 1-1789
  - “Memory section for initialize/terminate functions” on page 1-1794 (requires a license for Embedded Coder software and an ERT-based system target file)
  - “Memory section for execution functions” on page 1-1795 (requires a license for Embedded Coder software and an ERT-based system target file)
- Setting this parameter to **Nonreusable function** enables “Function with separate data” on page 1-1792 (requires a license for Embedded Coder software and an ERT-based system target file).

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function name options

Specify how Simulink Coder software is to name the function it generates for the subsystem.

If you have an Embedded Coder license, you can control function names with options on the Configuration Parameter **Code Generation** > **Symbols** pane.

### Settings

**Default:** Auto

#### Auto

Assign a unique function name using the default naming convention, *model*, *\_subsystem()*, where *model* is the name of the model and *subsystem* is the name of the subsystem (or that of an identical one when code is being reused).

If you select **Reusable function** for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **Function name options** must be set to **Auto**.

#### Use subsystem name

Use the subsystem name as the function name. By default, the function name uses the naming convention *model*, *\_subsystem*.

---

**Note** When a subsystem is a library block and the subsystem parameter “Function packaging” on page 1-1784 is set to **Reusable function**, if you set the **Use subsystem name** option, the code generator uses the name of the library block for the subsystem's function name and file name.

---

#### User specified

This option enables the **Function name** field. Enter any legal C or C++ function name, which must be unique.

### Dependencies

- This parameter requires a Simulink Coder license.
- Setting “Function packaging” on page 1-1784 to **Nonreusable function** or **Reusable function** enables this parameter.

- Setting this parameter to User specified enables the “Function name” on page 1-1788 parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Function name

Specify a unique, valid C or C++ function name for subsystem code.

### Settings

**Default:** ' '

Use this parameter if you want to give the function a specific name instead of allowing the Simulink Coder code generator to assign its own autogenerated name or use the subsystem name.

### Dependencies

- This parameter requires a Simulink Coder license.
- Setting “Function name options” on page 1-1786 to `User specified` enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## File name options

Specify how Simulink Coder software names the separate file for the function it generates for the subsystem.

### Settings

**Default:** Auto

#### Auto

Depending on the configuration of the subsystem and how many instances are in the model, **Auto** yields different results:

- If the code generator does *not* generate a separate file for the subsystem, the subsystem code is generated within the code module generated from the subsystem's parent system. If the subsystem's parent is the model itself, the subsystem code is generated within *model.c* or *model.cpp*.
- If you select **Reusable** function for the **Function packaging** parameter and your generated code is under source control, consider specifying a **File name options** value other than **Auto**. This prevents the generated file name from changing due to unrelated model modifications, which is problematic for using source control to manage configurations.
- If you select **Reusable** function for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **File name options** must be set to **Auto**.

#### Use subsystem name

The code generator generates a separate file, using the subsystem (or library block) name as the file name.

---

**Note** When **File name options** is set to **Use subsystem name**, the subsystem file name is mangled if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the file name for the subsystem consists of the subsystem name prefixed by the model name.

---

#### Use function name

The code generator uses the function name specified by **Function name options**) as the file name.

#### User specified

This option enables the **File name (no extension)** text entry field. The code generator uses the name you enter as the file name. Enter any file name, but do not include the `.c` or `.cpp` (or any other) extension. This file name need not be unique.

---

**Note** While a subsystem source file name need not be unique, you must avoid giving nonunique names that result in cyclic dependencies (for example, `sys_a.h` includes `sys_b.h`, `sys_b.h` includes `sys_c.h`, and `sys_c.h` includes `sys_a.h`).

---

#### Dependencies

- This parameter requires a Simulink Coder license.
- Setting “Function packaging” on page 1-1784 to **Nonreusable function** or **Reusable function** enables this parameter.
- Setting this parameter to **User specified** enables the “File name (no extension)” on page 1-1791 parameter.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## File name (no extension)

Specify how Simulink Coder software is to name the file for the function it generates for the subsystem.

### Settings

**Default:** ' '

- The filename that you specify does not have to be unique. However, avoid giving non-unique names that result in cyclic dependencies (for example, `sys_a.h` includes `sys_b.h`, `sys_b.h` includes `sys_c.h`, and `sys_c.h` includes `sys_a.h`).

### Dependencies

- This parameter requires a Simulink Coder license.
- Setting “File name options” on page 1-1789 to `User specified` enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function with separate data

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

### Settings

**Default:** Off

On

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and DWork data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

Off

Do not generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to **Nonreusable** function enables this parameter.
- Selecting this check box enables these parameters:
  - “Memory section for constants” on page 1-1796
  - “Memory section for internal data” on page 1-1798
  - “Memory section for parameters” on page 1-1800

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function interface

For this subsystem, specify whether the generated function uses arguments.

### Settings

**Default:** void\_void

void\_void

Generate a function without arguments and passes data as global variables. For example:

```
void subsystem_function(void)
```

Allow arguments

Generate a function that uses arguments instead of passing data as global variables. This specification reduces global RAM. It might reduce code size and improve execution speed, and allow the code generator to apply additional optimizations. For example:

```
void subsystem_function(real_T rtu_In1, real_T rtu_In2,  
                        real_T *rtu_Out1)
```

### Dependencies

- This parameter requires an Embedded Coder license and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to Nonreusable function enables this parameter.

### Command-Line Information

For the command-line information, see “Block-Specific Parameters” on page 6-105.

## Memory section for initialize/terminate functions

Indicate how the Embedded Coder software is to apply memory sections to the subsystem's initialization and termination functions.

### Settings

**Default:** `Inherit from model`

`Inherit from model`

Apply the root model's memory sections to the subsystem's function code

`Default`

Not apply memory sections to the subsystem's system code, overriding any model-level specification

`The memory section of interest`

Apply one of the model's memory sections to the subsystem

### Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation Memory Sections” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.
- These options can be useful for overriding the model's memory section settings for the given subsystem.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to `Nonreusable function` or `Reusable function` enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Memory section for execution functions

Indicate how the Embedded Coder software is to apply memory sections to the subsystem's execution functions.

### Settings

**Default:** `Inherit from model`

`Inherit from model`

Apply the root model's memory sections to the subsystem's function code

**Default**

Not apply memory sections to the subsystem's system code, overriding any model-level specification

**The memory section of interest**

Apply one of the model's memory sections to the subsystem

### Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation Memory Sections” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.
- These options can be useful for overriding the model's memory section settings for the given subsystem.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to `Nonreusable function` or `Reusable function` enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Memory section for constants

Indicate how the Embedded Coder software is to apply memory sections to the subsystem's data.

### Settings

**Default:** `Inherit from model`

`Inherit from model`

Apply the root model's memory sections to the subsystem's data

`Default`

Not apply memory sections to the subsystem's data, overriding any model-level specification

The memory section of interest

Apply one of the model's memory sections to the subsystem

### Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to `Nonreusable function` and selecting the “Function with separate data” on page 1-1792 check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Memory section for internal data

Indicate how the Embedded Coder software is to apply memory sections to the subsystem's data.

### Settings

**Default:** `Inherit from model`

`Inherit from model`

Apply the root model's memory sections to the subsystem's data

`Default`

Not apply memory sections to the subsystem's data, overriding any model-level specification

The memory section of interest

Apply one of the model's memory sections to the subsystem

### Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to `Nonreusable function` and selecting the “Function with separate data” on page 1-1792 check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Memory section for parameters

Indicate how the Embedded Coder software is to apply memory sections to the subsystem's data.

### Settings

**Default:** `Inherit from model`

`Inherit from model`

Apply the root model's memory sections to the subsystem's function code

`Default`

Not apply memory sections to the subsystem's system code, overriding any model-level specification

The memory section of interest

Apply one of the model's memory sections to the subsystem

### Tips

- The memory section that you specify applies to the corresponding global data structure in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

### Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- Setting “Function packaging” on page 1-1784 to `Nonreusable function` and selecting the “Function with separate data” on page 1-1792 check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Depends on the blocks in the subsystem
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, for enable and trigger ports if present
Code Generation	Yes

Introduced in R2007a

## Sum, Add, Subtract, Sum of Elements

Add or subtract inputs

### Library

Math Operations

### Description

The Sum block performs addition or subtraction on its inputs. This block can add or subtract scalar, vector, or matrix inputs. It can also collapse the elements of a signal.

You specify the operations of the block with the **List of signs** parameter. Plus (+), minus (-), and spacer (|) characters indicate the operations to be performed on the inputs:

- If there are two or more inputs, then the number of + and - characters must equal the number of inputs. For example, “+ - +” requires three inputs and configures the block to subtract the second (middle) input from the first (top) input, and then add the third (bottom) input.
- All nonscalar inputs must have the same dimensions. Scalar inputs will be expanded to have the same dimensions as the other inputs.
- A spacer character creates extra space between ports on the block's icon.
- For a round Sum block, the first input port is the port closest to the 12 o'clock position going in a counterclockwise direction around the block. Similarly, other input ports appear in counterclockwise order around the block.
- If only addition of all inputs is required, then a numeric parameter value equal to the number of inputs can be supplied instead of “+” characters.
- If only one input port is required, a single “+” or “-” collapses the element via the specified operation.

The Sum block first converts the input data type(s) to its accumulator data type, then performs the specified operations. The block converts the result to its output data type using the specified rounding and overflow modes.

## Calculation of Block Output

Output calculation for the Sum block depends on the number of block inputs and the sign of input ports:

If the Sum block has...	And...	The formula for output calculation is...	Where...
One input port	The input port sign is +	$y = e[0] + e[1] + e[2] \dots + e[m]$	$e[i]$ is the $i^{\text{th}}$ element of input $u$
	The input port sign is -	$y = 0.0 - e[0] - e[1] - e[2] \dots - e[m]$	
Two or more input ports	All input port signs are -	$y = 0.0 - u[0] - u[1] - u[2] \dots - u[n]$	$u[i]$ is the input to the $i^{\text{th}}$ input port
	The $k^{\text{th}}$ input port is the first port where the sign is +	$y = u[k] - u[0] - u[1] - u[2] - u[k-1] (+/-) u[k+1] \dots (+/-) u[n]$	

## Data Type Support

The Sum block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The inputs can be of different data types, unless you select the **Require all inputs to have the same data type** parameter. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Show data type assistant

Display the **Data Type Assistant**.

#### Settings

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Controlengineers.ir

## Icon shape

Designate the icon shape of the block.

### Settings

**Default:** round

rectangular

Designate the icon shape of the block as rectangular.

round

Designate the icon shape of the block as round.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## List of signs

Enter plus (+) and minus (-) characters.

### Settings

**Default:** |++

- Addition is the default operation, so if you only want to add the inputs, enter the number of input ports.
- For a single vector input, “+” or “-” will collapse the vector using the specified operation.
- Enter as many plus (+) and minus (-) characters as there are inputs.

### Tips

You can manipulate the positions of the input ports on the block by inserting spacers (|) between the signs in the **List of signs** parameter. For example, “++ | - -” creates an extra space between the second and third input ports.

### Dependencies

Entering only one element enables the **Sum over** parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sum over

Select dimension over which to perform the sum over operation.

### Settings

**Default:** All dimensions

All dimensions

Sum all input elements, yielding a scalar.

Specified dimension

Display the **Dimension** parameter, where you specify the dimension over which to perform the operation.

### Dependencies

Selecting Specified dimension enables the **Dimension** parameter.

List of signs (when it has only one element) enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Dimension

Specify the dimension over which to perform the operation.

### Settings

**Default:** 1

The block follows the same summation rules as the MATLAB `sum` function.

Suppose that you have a 2-by-3 matrix  $U$ .

- Setting **Dimension** to 1 results in the output  $Y$  being computed as:

$$Y = \sum_{i=1}^2 U(i, j)$$

- Setting **Dimension** to 2 results in the output  $Y$  being computed as:

$$Y = \sum_{j=1}^3 U(i, j)$$

If the specified dimension is greater than the dimension of the input, an error message appears.

### Dependencies

Setting **Sum over** to **Specified dimension** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

Controlengineers.ir

## Require all inputs to have the same data type

Require that all inputs have the same data type.

### Settings

**Default:** Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Lock data type settings against changes by the fixed-point tools

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Accumulator data type

Specify the accumulator data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Use internal rule to determine accumulator data type.

**Inherit:** Same as first input

Use data type of first input signal.

**double**

Accumulator data type is double.

**single**

Accumulator data type is single.

**int8**

Accumulator data type is int8.

**uint8**

Accumulator data type is uint8.

**int16**

Accumulator data type is int16.

**uint16**

Accumulator data type is uint16.

**int32**

Accumulator data type is int32.

**uint32**

Accumulator data type is uint32.

**fixdt(1,16,0)**

Accumulator data type is fixed point fixdt(1,16,0).

**fixdt(1,16,2^0,0)**

Accumulator data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Mode

Select the category of accumulator data to specify

### Settings

#### Default: Inherit

##### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables a list of possible values:

- Inherit via internal rule (default)
- Same as first input

##### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Specifies fixed-point data types.

##### Expression

Specifies expressions that evaluate to data types. Selecting **Expression** enables you to enter an expression.

### Dependency

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data to be signed.

#### Unsigned

Specify the fixed-point data to be unsigned.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Word length

Specify the bit size of the word that will hold the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependencies

Selecting **Mode** > **Fixed point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**
- **Bias**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** for the accumulator data type enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## **Bias**

Specify bias for the fixed-point data type.

### **Settings**

**Default:** 0

Specify any real number.

### **Dependencies**

Selecting **Scaling** > **Slope** and **bias** for the accumulator data type enables this parameter.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

See “Specifying a Fixed-Point Data Type” for more information.

Controlengineers.ir

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as first input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

---

**Note:** The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to **Inherit: Inherit same as accumulator**.

---

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**Inherit:** Same as first input

Use data type of first input signal.

**Inherit:** Same as accumulator

Output data type is the same as accumulator data type.

**double**

Output data type is **double**.

**single**

Output data type is **single**.

**int8**

Output data type is **int8**.

**uint8**

Output data type is **uint8**.

**int16**

Output data type is **int16**.

**uint16**

Output data type is **uint16**.

**int32**

Output data type is **int32**.

**uint32**

Output data type is **uint32**.

**fixdt(1,16,0)**

Output data type is fixed point **fixdt(1,16,0)**.

**fixdt(1,16,2^0,0)**

Output data type is fixed point **fixdt(1,16,2^0,0)**.

**<data type expression>**

Use a data type object, for example, **Simulink.NumericType**.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

For more information, see “Control Signal Data Types”.

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit via internal rule (default)
- Inherit via back propagation
- Same as first input
- Same as accumulator

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

#### Fixed point

Fixed-point data types.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Examples

### How the Sum Block Reorders Inputs

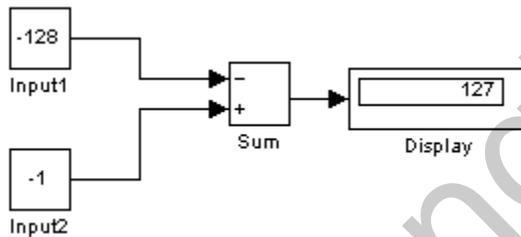

If you use - on the first input port, the Sum block reorders the inputs so that, if possible, the first input uses a + operation. For example, in the expression  $output = -a - b + c$ , the

Sum block reorders the inputs so that  $\text{output} = c - a - b$ . To initialize the accumulator, the Sum block uses the first + input port.

The block avoids performing a unary minus operation on the first operand **a** because doing so can change the value of **a** for fixed-point data types. In that case, the output value differs from the result of accumulating the values for **a**, **b**, and **c**.

**Tip:** To explicitly specify a unary minus operation for  $\text{output} = -a - b + c$ , you can use the **Unary Minus** block in the Math Operations library.

Suppose that you have the following model:

The following block parameters apply:

- Both Constant blocks, Input1 and Input 2, use **int8** for the **Output data type**.
- The Sum block uses **int8** for both **Accumulator data type** and **Output data type**.
- The Sum block has **Saturate on integer overflow** turned on.

The Sum block reorders the inputs so that the following operations occur and you get the ideal result of 127.

Step	Block Operation
1	Reorders inputs from $(-Input1 + Input2)$ to $(Input2 - Input1)$ .
2	Initializes the accumulator by using the first + input port: $Accumulator = \text{int8}(-1) = -1$
3	Continues to accumulate values: $Accumulator = Accumulator - \text{int8}(-128) = 127$

Step	Block Operation
4	Calculates the block output: $\text{Output} = \text{int8}(127) = 127$

If the Sum block does *not* reorder the inputs, the following operations occur instead and you get the nonideal result of 126.

Step	Block Operation
1	Initializes the accumulator by using the first input port: $\text{Accumulator} = \text{int8}(-(-128)) = 127$ Because saturation is on, the initial value of the accumulator saturates at 127 and does not wrap.
2	Continues to accumulate values: $\text{Accumulator} = \text{Accumulator} + \text{int8}(-1) = 126$
3	Calculates the block output: $\text{Output} = \text{int8}(126) = 126$

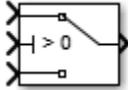

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Switch

Switch output between first input and third input based on value of second input

## Library

Signal Routing

## Description

### Types of Block Inputs

The Switch block passes through the first input or the third input based on the value of the second input. The first and third inputs are called *data inputs*. The second input is called the *control input*. Specify the condition under which the block passes the first input by using the **Criteria for passing first input** and **Threshold** parameters.

To immediately back propagate a known output data type to the first and third input ports, set the **Output data type** parameter to **Inherit: Inherit via internal rule** and select the **Require all data port inputs to have the same data type** check box.

### Limitations on Data Inputs

The sizes of the two data inputs can be different if you select **Allow different data input sizes** on the block dialog box. However, this block does not support variable-size input signals. Therefore, the size of each input cannot change during simulation.

If the data inputs to the Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name**

**mismatch** diagnostic to **error**. See “Connectivity Diagnostics Overview” for more information.

## Block Icon Appearance

The block icon helps you identify **Criteria for passing first input** and **Threshold** without having to open the block dialog box.

For information about port order for various block orientations, see “Port Location After Rotating or Flipping” in the Simulink documentation.

## Block Behavior for Boolean Control Input

When the control input is a Boolean signal, use one of these combinations of criteria and threshold value:

- $u2 \geq \text{Threshold}$ , where the threshold value equals 1
- $u2 > \text{Threshold}$ , where the threshold value equals 0
- $u2 \sim= 0$

Otherwise, the Switch block ignores the threshold and uses the Boolean input for signal routing. For a control input of 1, the block passes the first input, and for a control input of 0, the block passes the third input. In this case, the block icon changes *after compile time* and uses T and F to label the first and third inputs, respectively.

## Data Type Support

The control input can be of any data type that Simulink supports, including fixed-point and enumerated types. The control input cannot be complex. If the control input is enumerated, the **Threshold** parameter must be a value of the same enumerated type.

The data inputs can be of any data type that Simulink supports. If either data input is of an enumerated type, the other must be of the same enumerated type.

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Criteria for passing first input” on page 1-1842
- “Threshold” on page 1-1844
- “Enable zero-crossing detection” on page 1-1437
- “Sample time” on page 1-255
- “Require all data port inputs to have the same data type” on page 1-1847
- “Lock output data type setting against changes by the fixed-point tools” on page 1-203
- “Integer rounding mode” on page 1-252
- “Saturate on integer overflow” on page 1-254
- “Allow different data input sizes” on page 1-1852
- “Output minimum” on page 1-256
- “Output maximum” on page 1-257
- “Output data type” on page 1-1855
- “Mode” on page 1-1857
- “Data type override” on page 1-198
- “Signedness” on page 1-199
- “Word length” on page 1-200
- “Scaling” on page 1-193
- “Fraction length” on page 1-201
- “Slope” on page 1-202
- “Bias” on page 1-202

## Criteria for passing first input

Select the condition under which the block passes the first input. If the control input meets the condition set in the **Criteria for passing first input** parameter, the block passes the first input. Otherwise, the block passes the third input.

### Settings

**Default:**  $u2 > \text{Threshold}$

$u2 \geq \text{Threshold}$

Checks whether the control input is greater than or equal to the threshold value.

$u2 > \text{Threshold}$

Checks whether the control input is greater than the threshold value.

$u2 \sim= 0$

Checks whether the control input is nonzero.

---

**Note:** The Switch block does not support  $u2 \sim= 0$  mode for enumerated data types.

---

### Tip

When the control input is a Boolean signal, use one of these combinations of condition and threshold value:

- $u2 \geq \text{Threshold}$ , where the threshold value equals 1
- $u2 > \text{Threshold}$ , where the threshold value equals 0
- $u2 \sim= 0$

Otherwise, the Switch block ignores threshold values and uses the Boolean value for signal routing. For a value of 1, the block passes the first input, and for a value of 0, the block passes the third input. A warning message that describes this behavior also appears in the MATLAB Command Window.

### Dependencies

Selecting  $u2 \sim= 0$  disables the **Threshold** parameter.

## Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Threshold

Assign the switch threshold that determines which input the block passes to the output.

### Settings

**Default:** 0

**Minimum:** value from the **Output minimum** parameter

**Maximum:** value from the **Output maximum** parameter

### Tip

To specify a nonscalar threshold, use brackets. For example, the following entries are valid:

- [1 4 8 12]
- [MyColors.Red, MyColors.Blue]

### Dependencies

Setting **Criteria for passing first input** to u2  $\sim=0$  disables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Settings

**Default:** On

On  
Enable zero-crossing detection.

Off  
Do not enable zero-crossing detection.

### Command-Line Information

**Parameter:** ZeroCross

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

Controlengineers.ir

## Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

controlengineers.ir

## Require all data port inputs to have the same data type

Require all data inputs to have the same data type.

### Settings

**Default:** Off

On

Requires all data inputs to have the same data type.

Off

Does not require all data inputs to have the same data type.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Allow different data input sizes

Select this check box to allow input signals with different sizes.

### Settings

**Default:** Off

On

Allows input signals with different sizes, and propagates the input signal size to the output signal. If the two data inputs are variable-size signals, the maximum size of the signals can be equal or different.

Off

Inputs signals must be the same size.

### Command-Line Information

**Parameter:** AllowDiffInputSizes

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'off'

Controlengineers.ir

## Output minimum

Specify the minimum value that the block should output.

### Settings

**Default:** [ ]

The default value is [ ] (unspecified).

Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Tip

This number must be a finite real double scalar value.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output maximum

Specify the maximum value that the block should output.

### Settings

**Default:** [ ]

The default value is [ ] (unspecified).

Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Tip

This number must be a finite real double scalar value.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Uses the following rules to determine the output data type.

Data Type of First Input Port	Output Data Type
Has a larger positive range than the third input port	Inherited from the first input port
Has the same positive range as the third input port	Inherited from the third input port
Has a smaller positive range than the third input port	

Inherit: Inherit via back propagation

Uses data type of the driving block.

**double**

Specifies output data type is double.

**single**

Specifies output data type is single.

**int8**

Specifies output data type is int8.

**uint8**

Specifies output data type is uint8.

**int16**

Specifies output data type is int16.

**uint16**

Specifies output data type is uint16.

**int32**

Specifies output data type is `int32`.

`uint32`

Specifies output data type is `uint32`.

`fixdt(1,16,0)`

Specifies output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Specifies output data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Uses an enumerated data type, for example, Enum: `BasicColors`.

`<data type expression>`

Uses a data type object, for example, `Simulink.NumericType`.

### Tip

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Control Signal Data Types” for more information.

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Specifies inheritance rules for data types. Selecting **Inherit** enables a list of possible values:

- Inherit via internal rule (default)
- Inherit via back propagation

##### Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32

##### Fixed point

Specifies fixed-point data types.

##### Enumerated

Specifies enumerated data types. Selecting **Enumerated** enables you to enter a class name.

##### Expression

Specifies expressions that evaluate to data types. Selecting **Expression** enables you to enter an expression.

### Dependencies

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

Signed

Specifies the fixed-point data as signed.

Unsigned

Specifies the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

Large word sizes represent large values with greater precision than small word sizes.

### Dependencies

Selecting **Mode** > **Fixed point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

ControlEngineers.ir

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type” for more information.

## Bus Support

The Switch block is a bus-capable block. The data inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- All the buses must be equivalent (same hierarchy with identical names and attributes for all elements).
- All signals in a nonvirtual bus input to a Switch block must have the same sample time. The requirement holds even if the elements of the associated bus object specify inherited sample times.

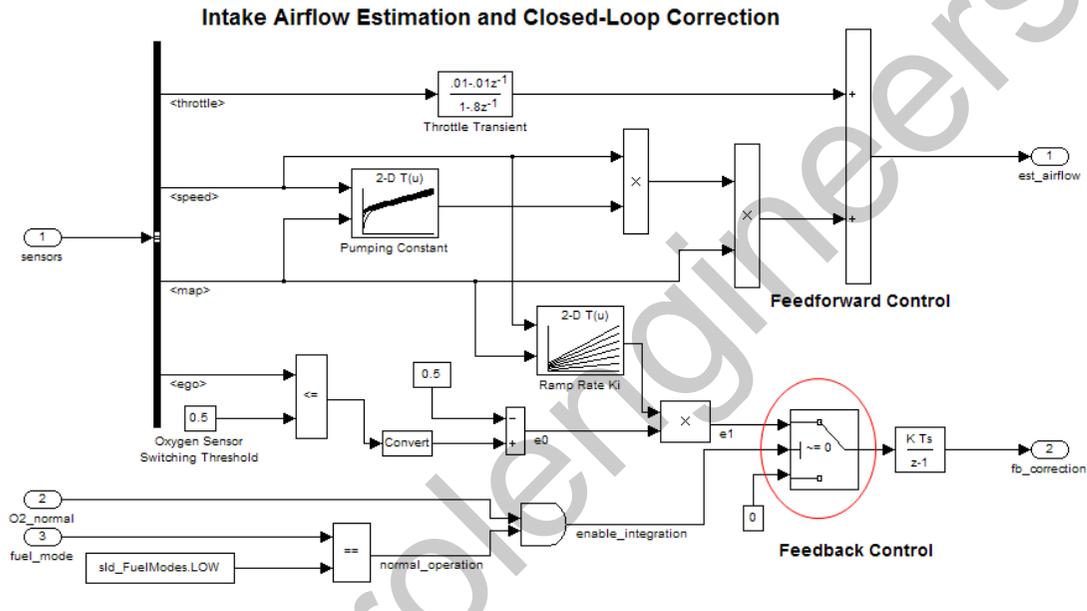

You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and **Bus-Capable Blocks** for more information.

You can use an array of buses as an input signal to a Switch block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. When using an array of buses with a Switch block, set the **Threshold** parameter to a scalar value.

## Examples

### Use of Boolean Input for the Control Port

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses a Switch block:

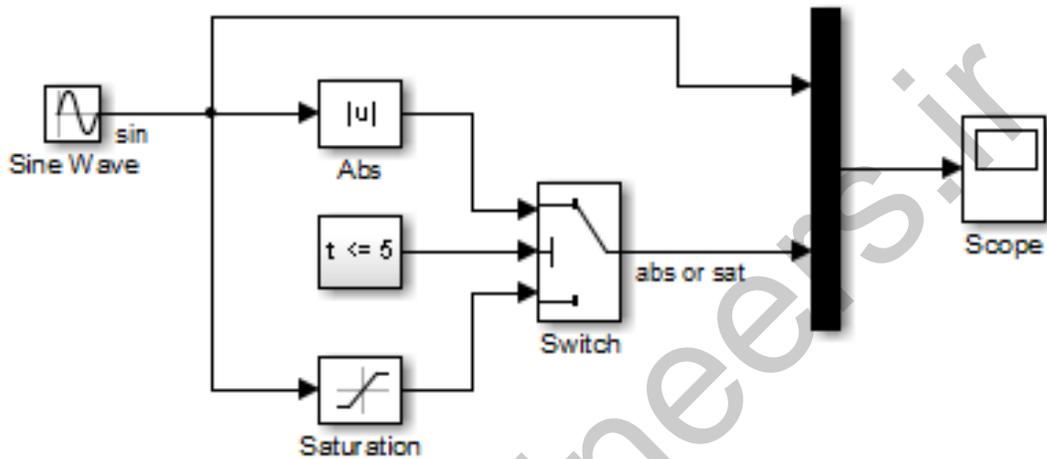

The value of the control port on the Switch block determines whether or not feedback correction occurs. The control port value depends on the output of the Logical Operator block.

When the Logical Operator block output is...	The control port of the Switch block is...	And feedback control...
TRUE	1	Occurs
FALSE	0	Does not occur

### Use of Simulation Time for the Control Port

The `sldemo_zeroxing` model uses a Switch block:

The value of the control port on the Switch block determines when the output changes from the first input to the third input.

When simulation time is...	The Switch block output is...
Less than or equal to 5	The first input from the Abs block
Greater than 5	The third input from the Saturation block

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

## See Also

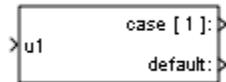

Multiport Switch

Introduced before R2006a

controlengineers.ir

## Switch Case

Implement C-like switch control flow statement

## Library

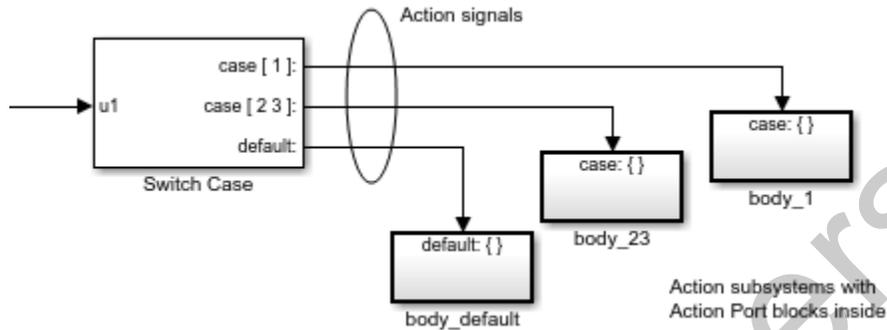

Ports & Subsystems

## Description

A Switch Case block receives a single input. Each output port is attached to a Switch Case Action Subsystem. Data outputs are action signals to Switch Case Action subsystems, which you create with Action Port blocks and subsystems.

The Switch Case block uses its input value to select a case condition that determines which subsystem to execute. The cases are evaluated top down starting with the first case. If a case value (in brackets) corresponds to the value of the input, its Switch Case Action Subsystem is executed.

If a default case exists, it executes if none of the other cases executes. Providing a default case is optional, even if the other case conditions do not exhaust every possible value. The following diagram shows a completed Simulink switch control flow statement:

Cases for the Switch Case block contain an implied break after their Switch Case Action subsystems are executed. Thus there is no fall-through behavior for the Simulink switch control flow statement as found in standard C switch statements. The following pseudocode represents generated code for the preceding switch control example:

```
switch (u1) {
  case [u1=1]:
    body_1;
    break;
  case [u1=2 or u1=3]:
    body_23;
    break;
  default:
    body_default;
}
```

To construct the Simulink switch control flow statement shown in the above example:

- 1 Place a Switch Case block in the current system and attach the input port labeled u1 to the source of the data you are evaluating.
- 2 Open the Switch Case block dialog box and update parameters:
  - a Populate the **Case conditions** field with the individual cases.
  - b To show a default case, select the **Show default case** check box.
- 3 Create a Switch Case Action Subsystem for each case port you added to the Switch Case block.

These consist of subsystems with Action Port blocks inside them. When you place the Action Port block inside a subsystem, the subsystem becomes an atomic subsystem with an input port labeled **Action**.

- 4 Connect each case output port and the default output port of the Switch Case block to the Action port of an Action subsystem.

Each connected subsystem becomes a case body. This is indicated by the change in label for the **Switch Case Action Subsystem** block and the Action Port block inside of it to the name `case{}`.

During simulation of a **switch** control flow statement, the Action signals from the Switch Case block to each **Switch Case Action Subsystem** turn from solid to dashed.

- 5 In each **Switch Case Action Subsystem**, enter the Simulink logic appropriate to the case it handles.

## Control Algorithm Execution Using Enumerated Signal

This example shows how to use a signal of an enumerated data type to control the execution of a block algorithm. For basic information about using enumerated data types in models, see “Use Enumerated Data in Simulink Models”.

When you use enumerated data in a Switch Case block, follow these best practices:

- Use the same enumerated type for the input `u1` and all of the case condition values.
- Use a different underlying integer for each of the enumerated values that you specify in the **Case conditions** box.

### Define Enumerated Type

Copy the enumerated type definition `ex_SwitchCase_MyColors` into a script file in your current folder.

```

classdef ex_SwitchCase_MyColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
        Mauve(3)
    end
end
    
```

```
end
end
```

Alternatively, you can use the function `Simulink.defineIntEnumType` to define the type.

```
Simulink.defineIntEnumType('ex_SwitchCase_MyColors',...
{'Red','Yellow','Blue','Mauve'},[0;1;2;3])
```

### Explore Example Model

- 1 Open the example model `ex_enum_switch_case`.
- 2 Open the Enumerated Constant block dialog box. The constant output value is `ex_SwitchCase_MyColors.Blue`.
- 3 Open the Switch Case block dialog box. The **Case conditions** box is set to a cell array containing three of the four possible enumeration members. The block has four outputs corresponding to the three specified enumeration members and a default case.
- 4 Open the Switch Case Action Subsystem blocks. The subsystems each contain a Constant block that uses a unique constant value.

### Control Execution During Simulation

- 1 In the Simulink Editor, set the simulation stop time to `Inf`.
- 2 Simulate the model. The Display block shows the value 5, which corresponds to the case `ex_SwitchCase_MyColors.Blue`.
- 3 In the Enumerated Constant block dialog box, set **Value** to `ex_SwitchCase_MyColors.Red` and click **Apply**. The Display block shows 19.
- 4 Set **Value** to `ex_SwitchCase_MyColors.Mauve` and click **Apply**. The Display block shows 3, which corresponds to the default case.

## Data Type Support

The input to the port labeled `u1` of a Switch Case block can be:

- A scalar value having a built-in data type that Simulink supports. The block does not support Boolean or fixed-point data types and truncates the numeric inputs to 32-bit signed integers.

- A scalar value of any enumerated data type, as described in “Control Algorithm Execution Using Enumerated Signal” on page 1-1871.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Case conditions

Specify the case conditions using MATLAB cell notation. For example, entering `{ 1, [ 7, 9, 4 ] }` specifies that output port `case[1]` is run when the input value is 1, and output port `case[7 9 4]` is run when the input value is 7, 9, or 4.

You can use colon notation to specify a range of integer case conditions. For example, entering `{ [ 1 : 5 ] }` specifies that output port `case[1 2 3 4 5]` is run when the input value is 1, 2, 3, 4, or 5.

Depending on block size, cases with long lists of conditions are displayed in shortened form in the Switch Case block, using a terminating ellipsis (...).

You can use the `enumeration` function to specify a case condition that includes a case for every value in an enumerated type.

### Show default case

If you select this check box, the default output port appears as the last case on the Switch Case block, allowing you to specify a default case. This case executes when the input value does not match any of the case values specified in the **Case conditions** field. With **Show default case** selected, a default output port always appears, even if the preceding cases exhaust all possibilities for the input value.

### Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

## Characteristics

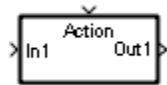

Data Types	Double   Single   Base Integer   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Controlengineers.ir

# Switch Case Action Subsystem

Represent subsystem whose execution is triggered by Switch Case block

## Library

Ports & Subsystems

## Description

This block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by a Switch Case block.

---

**Note:** All blocks in a Switch Case Action Subsystem must run at the same rate as the driving Switch Case block. You can achieve this by setting each block's sample time parameter to be either inherited (-1) or the same value as the Switch Case block's sample time.

---

For more information, see “Action Subsystem”, Switch Case block and “Use Control Flow Logic” in the “Creating a Model” chapter of the Simulink documentation.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes

Code Generation	Yes
-----------------	-----

Introduced before R2006a

controlengineers.ir

# Synchronous Subsystem

Represent subsystem that has synchronous reset and enable behavior

## Library

HDL Coder / HDL Subsystems

## Description

A Synchronous Subsystem is a subsystem that uses the **Synchronous** mode of the State Control block. If an **S** symbol appears in the subsystem, then it is synchronous.

To create a Synchronous Subsystem, add the block to your Simulink model from the HDL Subsystems block library. You can also add a State Control block with **State control** set to **Synchronous** inside a subsystem. For more information about the State Control block, see State Control.

## Data Type Support

See **Inport** for information on the data types accepted by a subsystem's input ports. See **Outport** for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

#### Settings

**Default:** FromPortIcon

none

Does not display port labels on the subsystem block.

FromPortIcon

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

FromPortBlockName

Display the name of the corresponding port block on the subsystem block.

SignalName

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Read/Write permissions

Control user access to the contents of the subsystem.

### Settings

**Default:** ReadWrite

#### ReadWrite

Enables opening and modification of subsystem contents.

#### ReadOnly

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

#### NoReadOrWrite

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

### Settings

**Default:** ' '

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

### Settings

**Default:** All

#### All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, Simulink.Signal objects).

#### ExplicitOnly

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

#### None

Do not resolve any workspace variable names.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

### Settings

**Default:** Off

On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

### Dependencies

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-1779.
- “Sample time (-1 for inherited)” on page 1-1782
- “Function packaging” on page 1-1784 (requires a Simulink Coder license)

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

### Settings

**Default:** On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

### Dependency

“Treat as grouped when propagating variant conditions” on page 1-1778 enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

### Settings

**Default:** Auto

Auto

Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

Inline

Simulink Coder software inlines the subsystem unconditionally.

### Nonreusable function

Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments depending on the “Function interface” on page 1-1793 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-1788 and “File name (no extension)” on page 1-1791. These functions are not reentrant.

### Reusable function

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
HDL Code Generation	Yes

## Tapped Delay

Delay scalar signal multiple sample periods and output all delayed versions

### Library

Discrete

### Description

The Tapped Delay block delays an input by the specified number of sample periods and outputs all the delayed versions. Use this block to discretize a signal in time or resample a signal at a different rate.

The block accepts one scalar input and generates an output vector that contains each delay. Specify the order of the delays in the output vector with the **Order output vector starting with** parameter:

- **Oldest** orders the output vector starting with the oldest delay version and ending with the newest delay version.
- **Newest** orders the output vector starting with the newest delay version and ending with the oldest delay version.

Specify the output vector for the first sampling period with the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior.

Specify the time between samples with the **Sample time** parameter. Specify the number of delays with the **Number of delays** parameter. A value of -1 instructs the block to inherit the number of delays by back propagation. Each delay is equivalent to the  $z^{-1}$  discrete-time operator, which the **Unit Delay** block represents.

## Data Type Support

The Tapped Delay block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Specify the initial output of the simulation. The **Initial condition** parameter is converted from a double to the input data type offline using round-to-nearest and saturation. Simulink software does not allow you to set the initial condition of this block to `inf` or `NaN`.

### Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in the online Simulink documentation for more information.

### Number of delays

Specify the number of discrete-time operators.

### Order output vector starting with

Specify whether to output the oldest delay version first, or the newest delay version first.

### Include current input in output vector

Select to include the current input in the output vector.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
------------	--

Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes, when <b>Include current input in output vector</b> check box is selected. No, otherwise.
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

# Terminate Function

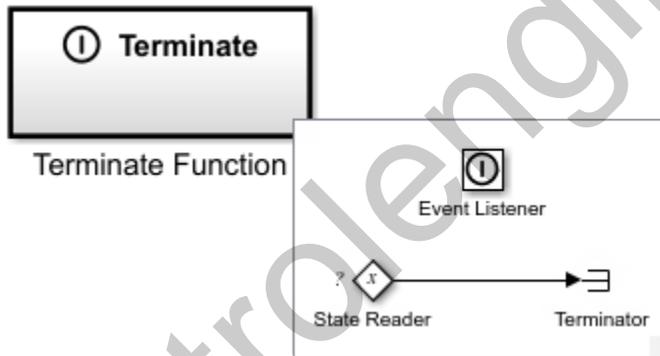

Execute contents on a model terminate event

**Library:** User-Defined Functions

## Description

The Terminate Function block is a pre-configured subsystem block that executes on a model terminate event. By default, the Terminate Function block includes an Event Listener block with **Event** set to **Terminate**, a Terminator block, and a State Reader block.

Replace the Terminator block with blocks to save the state value from the State Reader block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_terminate` function that is called once at the end of model execution.

## Terminator

Terminate unconnected output port

## Library

Sinks

## Description

Use the Terminator block to cap blocks whose output ports do not connect to other blocks. If you run a simulation with blocks having unconnected output ports, Simulink issues warning messages. Using Terminator blocks to cap those blocks helps prevent warning messages.

## Data Type Support

The Terminator block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Examples

The following Simulink examples show how to use the Terminator block:

- sldemo\_bounce
- sldemo\_fuelsys
- aero\_six\_dof

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

# Timed-Based Linearization

Generate linear models in base workspace at specific times

## Library

Model-Wide Utilities

## Description

This block calls `linmod` or `dlinmod` to create a linear model for the system when the simulation clock reaches the time specified by the **Linearization time** parameter. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Timed_Based_Linearization`, for example, `vdp_Timed_Based_Linearization`. The structure has the following fields:

Field	Description
a	The A matrix of the linearization
b	The B matrix of the linearization
c	The C matrix of the linearization

Field	Description
d	The D matrix of the linearization
StateName	Names of the model's states
OutputName	Names of the model's output ports
InputName	Names of the model's input ports
OperPoint	A structure that specifies the operating point of the linearization. The structure specifies the operating point time ( <code>OperPoint.t</code> ). The states ( <code>OperPoint.x</code> ) and inputs ( <code>OperPoint.u</code> ) fields are not used.
Ts	The sample time of the linearization for a discrete linearization

Use the Trigger-Based Linearization block if you need to generate linear models conditionally.

You can use state and simulation time logging to extract the model states and inputs at operating points. For example, suppose that you want to get the states of the f14 example model at linearization times of 2 seconds and 5 seconds.

- 1 Open the model and drag an instance of this block from the Model-Wide Utilities library and drop the instance into the model.
- 2 Open the block's parameter dialog box and set the **Linearization time** to 2 and 5.
- 3 Open the model's **Model Configuration Parameters** dialog box.
- 4 Select the **Data Import/Export** pane.
- 5 Check **States** and **Time** on the **Save to Workspace** control panel
- 6 Select OK to confirm the selections and close the dialog box.
- 7 Simulate the model.

At the end of the simulation, the following variables appear in the MATLAB workspace: `f14_Timed_Based_Linearization`, `tout`, and `xout`.

- 8 Get the indices to the operating point times by entering the following at the MATLAB command line:

```
ind1 = find(f14_Timed_Based_Linearization(1).OperPoint.t==tout);
ind2 = find(f14_Timed_Based_Linearization(1).OperPoint.t==tout);
```

- 9 Get the state vectors at the operating points.

```
x1 = xout(ind1,:);
```

```
x2 = xout(ind2,:);
```

## Data Type Support

Not applicable.

## Parameters

### Linearization time

Time at which you want the block to generate a linear model. Enter a vector of times if you want the block to generate linear models at more than one time step.

### Sample time (of linearized model)

Specify a sample time to create discrete-time linearizations of the model (see “Discrete-Time System Linearization” on page 2-38).

## Characteristics

Data Types	Not applicable
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	No

## See Also

Trigger-Based Linearization

Introduced in R2010a

## To Dataflow

Open a dataflow region to use data-driven simulation

**Library:** DSP System Toolbox / Dataflow

### Description

A To Dataflow block opens a dataflow region where simulation is data-driven instead of time-based simulation. Blocks and signal lines inside of a dataflow region have no sample time, therefore blocks execute only when they have sufficient data available.

Data-driven simulation makes dataflow regions amenable to multithreaded execution, especially in applications with streaming computation intensive signal processing workloads. Dataflow regions execute parts of the region with no data dependencies in parallel.

Use the From Dataflow block to specify the design latency of the region. The pipelining delay added to the model generates concurrency by breaking data dependencies between blocks. Fewer data dependencies gives Simulink more flexibility in assigning blocks to threads and generally allows Simulink to use more threads.

### Ports

#### Input

##### Port\_1 — Input signal

time-based signal

Time-based signal to be converted to a data-driven signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point` | `enumerated` | `bus`

#### Output

##### Port\_2 — Output signal

data-driven signal

Data-driven signal that has been converted from a time-based signal. This output signal is part of a dataflow region in the model.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

## To File

Write data to file

## Library

Sinks

## Description

The To File block inputs a signal and writes the signal data into a MAT-file. Use the To File block to log signal data.

The To File block icon shows the name of the output file.

The block writes to the output file incrementally, with minimal memory overhead during simulation. If the output file exists when the simulation starts, the block overwrites the file. The file automatically closes when simulation is complete or paused. If simulation terminates abnormally, the To File block saves the data it has logged up until the point of the abnormal termination.

---

**Tip:** If MATLAB encounters memory issues when you log a large number of signals in a long simulation that has many time steps, consider logging to persistent storage. When you log to persistent storage, the **Dataset** format logging data is stored in a MAT-file. Compared to logging to persistent storage, connecting a To File block to signals:

- Is a per-signal approach that can clutter a model with several To File blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, compared to the one MAT-file that logging to persistent storage uses.

For details, see “Log Data to Persistent Storage”.

---

## Specifying the Format for Writing Data

Use the **Save format** parameter to specify the format for writing data:

- **Timeseries** (default)
- **Array**

Use the **Array** format only for vector, double, noncomplex signals. To save bus data, use the **Timeseries** format.

For the **Timeseries** format, the To File block:

- Writes data in a MATLAB **timeseries** object
- Supports writing multidimensional, real or complex output values
- Supports writing output values that have any built-in data type, including **Boolean**, enumerated (**enum**), and fixed-point data with a word length of up to 32 bits
- For bus input signals, creates a MATLAB structure that matches the bus hierarchy. Each leaf of the structure is a MATLAB **timeseries** object.

For the **Array** format, the To File block:

- Writes data into a matrix containing two or more rows. The matrix has the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u_{1_1} & u_{1_2} & \dots & u_{1_{final}} \\ \dots & & & \\ u_{n_1} & u_{n_2} & \dots & u_{n_{final}} \end{bmatrix}$$

Simulink writes one column to the matrix for each data sample. The first element of the column contains the time stamp. The remainder of the column contains data for the corresponding output values.

- Supports writing data that is one-dimensional, double, and noncomplex.

The following table shows how simulation mode support depends on the **Save format** value.

Simulation Mode	Timeseries	Array
Normal	Supported.	Supported.

Simulation Mode	Timeseries	Array
Accelerator	Supported.	Supported.
Rapid Accelerator	Supported.	Supported.
Software-in-the-Loop (SIL)	Not supported.	Supported if MAT-file logging is enabled.
Processor-in-the-Loop (PIL)	Not supported.	Supported if MAT-file logging is available and enabled.
External	Not supported.	Supported if MAT-file logging is enabled.
RSim target	Supported.	Supported if MAT-file logging is enabled.

## Controlling When Data Is Written to the File

The To File block **Decimation** and **Sample Time** parameters control when data is written to the file.

The To File block does not log data outside of the intervals specified by the **Model Configuration Parameters > Data Import/Export > Logging intervals** parameter. The block stores the logged data in the file associated with the block instead of storing the data in the variable that you specify for the **Single simulation output** parameter.

## Saving Data for Use by a From File Block

The From File block can use data written by a To File block in any format (Timeseries or Array) without any modifications to the data or other special provisions.

## Saving Data for Use by a From Workspace Block

The From Workspace block can read data that is in the Array format and is the transposition of the data written by the To File block. To provide the required format, use MATLAB commands to load and transpose the data from the MAT-file.

## Simulation Stepper Interaction with To File Block

If you pause using the Simulation Stepper, the To File block captures the simulation data up to the point of the pause. When you step back, the To File data file no longer contains any simulation data past the new reduced time of the last output.

## Limitations of To File blocks in a Referenced Model

When a To File block is in a referenced model, that model must be a single-instance model. Only one instance of such a model can exist in a model hierarchy. See “General Reusability Limitations” for more information.

## Compressing MAT-File Data

To avoid the overhead of compressing data in real time, the To File block writes an uncompressed Version 7.3 MAT-file. To compress the data within the MAT-file, load and save the file in MATLAB. The resaved file is smaller than the original MAT-file that the To File block created, because the **Save** command compresses the data in the MAT-file.

## Saving Bus Data

The To File block supports virtual and nonvirtual bus input.

To save bus data, set the **Save format** parameter to **Timeseries**.

If the input signal is a bus, then the To File block creates a MATLAB structure that matches the bus hierarchy. Each leaf of the structure is a MATLAB `timeseries` object.

## Pausing a Simulation

After pausing a simulation, do not alter any file that a To File block logs into. For example, do not save such a file with the MATLAB `save` command. Altering the file can cause an error when you resume the simulation. If you want to alter the file after pausing, copy the file and work with the copy of the file.

## Generating Code

To generate code for a To File block, on the **Code Generation > Interface** pane, you must select the configuration parameter “MAT-file logging” (Simulink Coder).

## Data Type Support

The To File block accepts real or complex signal data of any data type that Simulink supports, with the exception that the word length for fixed-point data must be 32 bits or less.

The To File block accepts bus data.

## Parameters

### File name

The path or file name of the MAT-file in which to store the output. On UNIX systems, the pathname can start with a tilde (~) character signifying your home folder. The default file name is `untitled.mat`. If you specify a file name without path information, Simulink stores the file in the MATLAB working folder. (To determine the working folder, type `pwd` at the MATLAB command line.) If the file already exists, Simulink overwrites it.

### Variable name

The name of the matrix contained in the named file. The default name is `ans`.

### Save format

The data format that the To File block uses for writing data:

- Timeseries (default)
- Array

### Decimation

The decimation factor,  $n$ , where  $n$  specifies writing data at every  $n$ th time that the block executes. The default decimation is 1, which writes data at every time step.

## Sample time

Specifies the sample period and offset at which to collect points. This parameter is useful when you are using a variable-step solver where the interval between time steps might not be constant. The default is -1, which inherits the sample time from the driving block. See “Specify Sample Time” for more information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

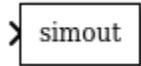

## See Also

“Save Runtime Data from Simulation”, “Convert Logged Data to Dataset Format”, From File, From Workspace, To Workspace

Introduced before R2006a

## To Workspace

Write data to workspace

## Library

Sinks

## Description

The To Workspace block inputs a signal and writes the signal data to a workspace. During the simulation, the block writes data to an internal buffer. When the simulation is completed or paused, that data is written to the workspace. Data is not available until the simulation is stopped or paused.

- For menu-based simulation, data is written in the MATLAB base workspace.
- A `sim` command in a MATLAB function sends data logged with the To Workspace block to the workspace of the calling function, not to the MATLAB (base) workspace. To send the logged data to the base workspace, use an `assignin` command in the function. For example:

```
function myfunc
    a = sim('mTest','SimulationMode','normal');
    b = a.get('simout')
    assignin('base','b',b);
end
```

The block icon shows the name of the variable to which the data is written. To specify the name of the workspace variable to which the To Workspace block writes the data, use the **Variable name** parameter.

To specify the data format of the variable, use the **Save format** parameter. You can specify to save the data in one of the following formats:

- A MATLAB timeseries object (or structure of MATLAB timeseries objects for bus data)

- An array
- Structure
- Structure with time

From one of these formats, you can convert the data to **Dataset** format. Converting to **Dataset** format makes it easier to post-process with other logged data (for example, logged states), which can also use **Dataset** format. For more information, see “Convert Logged Data to Dataset Format”. You can also use signal logging with a variable-size signal exception.

## Saving Data for Use by a From Workspace Block

To use a **From Workspace** block to read into Simulink the sample-based data that was saved by a **To Workspace** block in a previous simulation, in the **To Workspace** block, specify time information using the **Timeseries** or **Structure with time** format.

## Controlling the Amount of Data Saved

If you specify intervals with the **Model Configuration Parameters > Data Import/Export > Logging intervals** parameter, the block does not log data outside of the intervals. For example, the block logs no data if the intervals are empty ([ ]).

For variable-step solvers, to control the amount of data available to the **To Workspace** block, use the **Model Configuration Parameters > Data Import/Export > Additional parameters > Output options** parameter. For example, to have Simulink write data at identical time points over multiple simulations, select the **Produce specified output only** option.

Then use **To Workspace** block parameters to control when and how much of this data the block writes:

- Use the **Limit data points to last** parameter to specify how many sample points to save. If the simulation generates more data points than the specified maximum, the simulation saves only the most recently generated samples. To capture all the data, set this value to **inf**.
- Use the **Decimation** parameter to have the **To Workspace** block write data at every  $n$ th sample, where  $n$  is the decimation factor. The default decimation, 1, writes data at every time hit.

- Use the **Sample time** parameter to specify a sampling interval at which to collect points. This parameter is useful when you are using a variable-step solver where the interval between time hits might not be the same. The default value of -1 causes the block to inherit the sample time from the driving block when determining the points to write. See “Specify Sample Time” in the online documentation for more information.

For example, suppose you have a simulation where the start time is 0, the **Limit data points to last** is 100, the **Decimation** is 1, and the **Sample time** is 0.5. The To Workspace block collects a maximum of 100 points, at time values of 0, 0.5, 1.0, 1.5, ..., seconds. Specifying a **Decimation** value of 1 directs the block to write data at each step.

In a similar example, the **Limit data points to last** is 100 and the **Sample time** is 0.5, but the **Decimation** is 5. In this example, the block collects up to 100 points, at time values of 0, 2.5, 5.0, 7.5, ..., seconds. Specifying a **Decimation** value of 5 directs the block to write data at every fifth sample. The sample time ensures that data is written at these points.

In another example, all parameters are as defined in the first example except that the **Limit data points to last** is 3. In this case, only the last three sample points collected are written to the workspace. If the simulation stop time is 100, data corresponds to times 99.0, 99.5, and 100.0 seconds (three points).

## MAT-File Logging

When you enable the **Configuration Parameters > All Parameters > MAT-file logging** parameter, To Workspace logs its data to a MAT-file. For information about this parameter, in the Simulink Coder documentation, see “MAT-file logging” (Simulink Coder).

## Frame-Based Signals

By default, the To Workspace block treats input signals as sample-based.

To have the To Workspace block treat input signals as frame-based, set:

- 1 **Save format** to either **Array** or **Structure**
- 2 **Save 2-D signals as** to 2-D array (concatenate along first dimension)

## Data Type Support

The To Workspace block can save to the MATLAB workspace real or complex inputs of any data type that Simulink supports, including fixed-point and enumerated data types, as well as bus objects.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Variable name

Specify the name of the variable for the saved the data.

### Limit data points to last

Specify the maximum number of input samples to save. The default is `inf`.

### Decimation

Specify the decimation factor. The default is 1.

### Save format

Specify one of these formats for saving simulation output to the workspace:

- **Timeseries** (Default)

Save non-bus signals as a MATLAB timeseries object and bus signals as a structure of MATLAB timeseries objects.

- **Array**

Save the input as an N-dimensional array where N is one more than the number of dimensions of the input signal. For example, if the input signal is a vector, the resulting workspace array is two-dimensional. If the input signal is a matrix, then the array is three-dimensional.

How Simulink stores samples in the array depends on whether the input signal is a scalar, vector, or matrix. If the input is a scalar or a vector, each input sample

is output as a row of the array. For example, suppose that the name of the output array is `simout`. Then, `simout(1, :)` corresponds to the first sample, `simout(2, :)` corresponds to the second sample, and so on. If the input signal is a matrix, time corresponds to the third dimension. For example, suppose again that `simout` is the name of the resulting workspace array. Then, `simout(:, :, 1)` is the value of the input signal at the first sample point; `simout(:, :, 2)` is the value of the input signal at the second sample point; and so on.

If you select **Array**, the **Save 2-D signals** as parameter appears.

To treat input signals as frame-based, set **Save format** to either **Array** or **Structure** and set the **Save 2-D signals** parameter to **2-D array (concatenate along first dimension)**.

- **Structure**

This format consists of a structure with three fields:

- **time** — This field is empty for this format.
- **signals** — A structure with three fields: **values**, **dimensions**, and **label**. The **values** field contains the array of signal values. The **dimensions** field specifies the dimensions of the corresponding signals. The **label** field contains the label of the input line.
- **blockName** — Name of the To Workspace block

If you select **Structure**, the **Save 2-D signals** as parameter appears.

To treat input signals as frame-based, set **Save format** to either **Structure** or **Array** and set the **Save 2-D signals** parameter to **2-D array (concatenate along first dimension)**.

- **Structure With Time**

This format is the same as **Structure**, except that the time field contains a vector of simulation time hits.

To read To Workspace block output directly with a From Workspace block, use either the **Timeseries** or **Structure with Time** format. For details, see “Comparison of Signal Loading Techniques”.

**Structure with Time** format does not support frame-based signals. Use **Array** or **Structure** format instead.

The following table shows how simulation mode support depends on the **Save format** value.

Simulation Mode	Timeseries	Array, Structure, or Structure With Time
Normal	Supported.	Supported.
Accelerator	Supported.	Supported only in top model, not referenced models.
Rapid Accelerator	Not supported.	Supported only in top model, not referenced models.
Software-in-the-Loop (SIL)	Not supported.	If MAT-file logging is enabled, supported only in top model, not referenced models.
Processor-in-the-Loop (PIL)	Not supported.	If MAT-file logging is available and enabled, supported only in top model, not referenced models.
External	Not supported.	Supported only in top model, not referenced models.
Simulink Coder Targets	Not supported.	If MAT-file logging is enabled, supported only in top model, not referenced models.

## Save 2-D signal as

If you set **Save format** to Array or Structure, the **Save 2-D signals as** parameter appears.

Specify one of these formats for saving 2-D signals to the workspace:

- 3-D array (concatenate along third dimension) (Default)

This setting is well-suited for sample-based signals. Data is concatenated along the third dimension. For example, 2-by-4 matrix input for 10 samples is stored as a 2x4x10 array.

- 2-D array (concatenate along first dimension)

This setting is well-suited for frame-based signals. The data is concatenated along the first dimension. For example, 2-by-4 matrix input for 10 samples is stored as a 20x4 array

- Inherit from input (this choice will be removed – see release notes)

This setting is for backward compatibility. To configure this block to treat input signals as frame-based in future releases, set this parameter to **2-D array (concatenate along first dimension)**. To configure this block to treat input signals as sample-based in future releases, set this parameter to **3-D array (concatenate along third dimension)**.

When the **Save format** is set to **Array** or **Structure**, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, *K* represents the value of the **Limit data points to last** parameter.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
<i>M</i> -by- <i>N</i> matrix	2-D array (concatenate along first dimension)	<i>K</i> -by- <i>N</i> matrix.  If you set the <b>Limit data points to last</b> parameter to <b>inf</b> , <i>K</i> represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size ( <i>M</i> ) by the total number of <i>M</i> -by- <i>N</i> inputs acquired by the block.
<i>M</i> -by- <i>N</i> matrix	3-D array (concatenate along third dimension)	<i>M</i> -by- <i>N</i> -by- <i>K</i> array.  If you set the <b>Limit data points to last</b> parameter to <b>inf</b> , <i>K</i> represents the total number of <i>M</i> -by- <i>N</i> inputs acquired by the end of the simulation.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
Length- $N$ unoriented vector	Any setting	$K$ -by- $N$ matrix
$N$ -dimensional array where $N > 2$	Any setting	Array with $N+1$ dimensions, where the size of the last dimension is equal to $K$ . If you set the <b>Limit data points to last</b> parameter to <code>inf</code> , $K$ represents the total number of $M$ -by- $N$ inputs acquired by the end of simulation

## Log fixed-point data as a fi object

By default, the To Workspace block logs fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. If you clear this parameter, fixed-point data is logged to the workspace as `double`.

## Sample time

Specify the sample period and offset at which to collect data. This parameter is useful when you are using a variable-step solver where the interval between time hits might not be constant. The default is `-1`, which inherits the sample time from the driving block. See “Specify Sample Time” for more information.

## Examples

The `sldemo_varsize_basic` example shows how to use the To Workspace block.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter

Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	No

# Toggle Switch

Set on/off values to tune parameters or variables

On

Off

## Library

Dashboard

## Description

The Toggle Switch block enables you to control tunable parameters and variables in your model during simulation. The block has two states that can be set to two different values.

To control a tunable parameter or variable using the Toggle Switch block, double-click the Toggle Switch block to open the dialog box. Select a block in the model canvas. The tunable parameter or variable appears in the dialog box **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable to the block.

## Limitations

The Toggle Switch block has these limitations, which you can work around.

Limitation	Workaround
You cannot save the block connections or properties in model files that use the MDL format.	Save the model file to SLX format to be able to save connections and properties.

Limitation	Workaround
Parameters that index a variable array do not appear in the <b>Connection</b> table.	For example, a block parameter specified using the variable <code>engine(1)</code> will not appear in the table because the parameter uses an index of the variable <code>engine</code> , which is not a scalar variable. To make the parameter appear in the <b>Connection</b> table, change the block parameter field to a scalar variable, such as <code>engine_1</code> .

Dashboard blocks cannot connect to blocks that are commented out.

Dashboard blocks cannot connect to signals inside reference models.

## Parameters

### Connection

Select a block to connect and control a tunable parameter or variable.

To control a tunable parameter or variable, select a block in the model. The tunable parameter or variable appears in the **Connection** table. Select the option button next to the tunable parameter or variable you want to control. Click **Apply** to connect the tunable parameter or variable.

### Settings

The table has a row for the tunable parameter or variable connected to the block. If there are no tunable parameters or variables selected in the model or the block is not connected to any tunable parameters or variables, then the table is empty.

### States

Switch values and labels.

### Settings

**Default Labels:** Off and On

### **Default Values:** 0 and 1

By default, the **Off** state label corresponds to the set value of 0, and the **On** state label corresponds to the set value of 1.

The state labels appear on the outside of the switch. You can change the state labels to another character vector. You can change the state values to any real value that is between negative `realmax` and positive `realmax`.

### **Label**

Position of the block label or instructional text if the block is not connected.

#### **Settings**

##### **Default:** Top

##### Top

Show the label at the top of the block.

##### Bottom

Show the label at the bottom of the block.

##### Hide

Do not show the label or instructional text when the block is not connected.

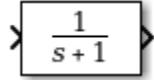

### **Examples**

For more information on using blocks from the Dashboard library, see “Tune and Visualize Your Model with Dashboard Blocks”.

#### **Introduced in R2015a**

## Transfer Fcn

Model linear system by transfer function

## Library

Continuous

## Description

The Transfer Fcn block models a linear system by a transfer function of the Laplace-domain variable  $s$ . The block can model single-input single-output (SISO) and single-input multiple output (SIMO) systems.

## Conditions for Using This Block

The Transfer Fcn block assumes the following conditions:

- The transfer function has the form

$$H(s) = \frac{y(s)}{u(s)} = \frac{num(s)}{den(s)} = \frac{num(1)s^{nn-1} + num(2)s^{nn-2} + \dots + num(nn)}{den(1)s^{nd-1} + den(2)s^{nd-2} + \dots + den(nd)}$$

where  $u$  and  $y$  are the system input and outputs, respectively,  $nn$  and  $nd$  are the number of numerator and denominator coefficients, respectively.  $num(s)$  and  $den(s)$  contain the coefficients of the numerator and denominator in descending powers of  $s$ .

- The order of the denominator must be greater than or equal to the order of the numerator.
- For a multiple-output system, all transfer functions have the same denominator and all numerators have the same order.

## Modeling a Single-Output System

For a single-output system, the input and output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the numerator coefficients of the transfer function in the **Numerator coefficients** field.
- 2 Enter a vector for the denominator coefficients of the transfer function in the **Denominator coefficients** field.

## Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix in the **Numerator coefficients** field.

Each *row* of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.

- 2 Enter a vector of the denominator coefficients common to all transfer functions of the system in the **Denominator coefficients** field.

## Specifying Initial Conditions

A transfer function describes the relationship between input and output in Laplace (frequency) domain. Specifically, it is defined as the Laplace transform of the response (output) of a system with zero initial conditions to an impulse input.

Operations like multiplication and division of transfer functions rely on zero initial state. For example, you can decompose a single complicated transfer function into a series of simpler transfer functions. Apply them sequentially to get a response equivalent to that of the original transfer function. This will not be correct if one of the transfer functions assumes a non-zero initial state. Furthermore, a transfer function has infinitely many time domain realizations, most of whose states do not have any physical meaning.

For these reasons, Simulink presets the initial conditions of the Transfer Fcn block to zero. To specify initial conditions for a given transfer function, convert the transfer function to its controllable, canonical state-space realization using `tf2ss`. Then, use the State-Space block. The `tf2ss` utility provides the A, B, C, and D matrices for the system.

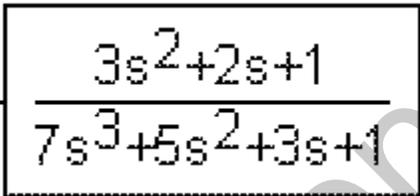

For more information, type `help tf2ss` or see the Control System Toolbox™ documentation.

## Transfer Function Display on the Block

The Transfer Fcn block displays the transfer function depending on how you specify the numerator and denominator parameters.

- If you specify each parameter as an expression or a vector, the block shows the transfer function with the specified coefficients and powers of  $s$ . If you specify a variable in parentheses, the block evaluates the variable.

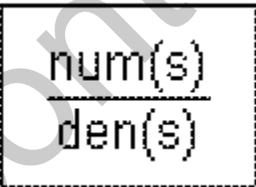

For example, if you specify **Numerator coefficients** as `[3,2,1]` and **Denominator coefficients** as `(den)`, where `den` is `[7,5,3,1]`, the block looks like this:

$$\frac{3s^2 + 2s + 1}{7s^3 + 5s^2 + 3s + 1}$$

- If you specify each parameter as a variable, the block shows the variable name followed by  $(s)$ .

For example, if you specify **Numerator coefficients** as `num` and **Denominator coefficients** as `den`, the block looks like this:

$$\frac{\text{num}(s)}{\text{den}(s)}$$

## Data Type Support

The Transfer Fcn block accepts and outputs signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Numerator coefficients

Define the row vector of numerator coefficients.

#### Settings

**Default:** [ 1 ]

#### Tips

- For a single-output system, enter a vector for the numerator coefficients of the transfer function.
- For a multiple-output system, enter a matrix. Each row of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.

#### Command-Line Information

**Parameter:** Numerator

**Type:** vector or matrix

**Value:** '[ 1 ]'

**Default:** '[ 1 ]'

#### See Also

See the Transfer Fcn block reference page for more information.

## Denominator coefficients

Define the row vector of denominator coefficients.

### Settings

**Default:** [1 1]

### Tips

- For a single-output system, enter a vector for the denominator coefficients of the transfer function.
- For a multiple-output system, enter a vector containing the denominator coefficients common to all transfer functions of the system.

### Command-Line Information

**Parameter:** Denominator

**Type:** vector

**Value:** '[1 1]'

**Default:** '[1 1]'

## Absolute tolerance

Specify the absolute tolerance for computing block states.

### Settings

**Default:** auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

### Command-Line Information

**Parameter:** AbsoluteTolerance

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

## State Name (e.g., 'position')

Assign a unique name to each state.

### Settings

**Default:** ' '

If this field is blank, no name assignment occurs.

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

### Command-Line Information

**Parameter:** ContinuousStateAttributes

**Type:** character vector

**Value:** ' ' | user-defined

**Default:** ' '

## Examples

The following Simulink examples show how to use the Transfer Fcn block:

- slxAircraftExample
- sldemo\_absbrake

- penddemo

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Only if the lengths of the <b>Numerator coefficients</b> and <b>Denominator coefficients</b> parameters are equal
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Discrete Transfer Fcn

## Transfer Fcn Direct Form II

Implement Direct Form II realization of transfer function

$$\frac{0.2+0.3z^{-1}+0.2z^{-2}}{1-0.9z^{-1}+0.6z^{-2}}$$

### Library

Additional Math & Discrete / Additional Discrete

### Description

The Transfer Fcn Direct Form II block implements a Direct Form II realization of the transfer function that the **Numerator coefficients** and **Denominator coefficients** **excluding lead** parameters specify. The block supports only single input-single output (SISO) transfer functions.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

### Data Type Support

The Transfer Fcn Direct Form II block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Numerator coefficients

Specify the numerator coefficients.

### Denominator coefficients excluding lead

Specify the denominator coefficients, excluding the leading coefficient, which must be 1.0.

### Initial condition

Set the initial condition.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Transfer Fcn Direct Form II Time Varying

Implement time varying Direct Form II realization of transfer function

## Library

Additional Math & Discrete / Additional Discrete

## Description

The Transfer Fcn Direct Form II Time Varying block implements a Direct Form II realization of the specified transfer function. The block supports only single input-single output (SISO) transfer functions.

The input signal labeled Den No Lead contains the denominator coefficients of the transfer function. The full denominator has a leading coefficient of one, but it is excluded from the input signal. For example, a denominator of  $[1 \ -1.7 \ 0.72]$  is represented by a signal with the value  $[-1.7 \ 0.72]$ . The input signal labeled Num contains the numerator coefficients. The data types of the numerator and denominator coefficients can be different, but the length of the numerator vector and the full denominator vector must be the same. Pad the numerator vector with zeros, if needed.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

## Data Type Support

The Transfer Fcn Direct Form II Time Varying block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Initial condition

Set the initial condition.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

## Transfer Fcn First Order

Implement discrete-time first order transfer function

### Library

Discrete

### Description

The Transfer Fcn First Order block implements a discrete-time first order transfer function of the input. The transfer function has a unity DC gain.

### Data Type Support

The Transfer Fcn First Order block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

#### Pole (in Z plane)

Set the pole.

### Initial condition for previous output

Set the initial condition for the previous output.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

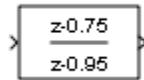

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Transfer Fcn Lead or Lag

Implement discrete-time lead or lag compensator

### Library

Discrete

### Description

The Transfer Fcn Lead or Lag block implements a discrete-time lead or lag compensator of the input. The instantaneous gain of the compensator is one, and the DC gain is equal to  $(1-z)/(1-p)$ , where  $z$  is the zero and  $p$  is the pole of the compensator.

The block implements a lead compensator when  $0 < z < p < 1$ , and implements a lag compensator when  $0 < p < z < 1$ .

### Data Type Support

The Transfer Fcn Lead or Lag block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

#### Pole of compensator (in Z plane)

Set the pole.

### Zero of compensator (in Z plane)

Set the zero.

### Initial condition for previous output

Set the initial condition for the previous output.

### Initial condition for previous input

Set the initial condition for the previous input.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

### Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

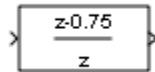

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## Transfer Fcn Real Zero

Implement discrete-time transfer function that has real zero and no pole

### Library

Discrete

### Description

The Transfer Fcn Real Zero block implements a discrete-time transfer function that has a real zero and effectively no pole.

### Data Type Support

The Transfer Fcn Real Zero block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

### Parameters

#### Zero (in Z plane)

Set the zero.

#### Initial condition for previous input

Set the initial condition for the previous input.

#### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

---

**Note:** Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input **u**. All other input signals must be sample based.

Input Signal <b>u</b>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

**Saturate to max or min when overflows occur**

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

**Characteristics**

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

# Transport Delay

Delay input by given amount of time

## Library

Continuous

## Description

The Transport Delay block delays the input by a specified amount of time. You can use this block to simulate a time delay. The input to this block should be a continuous signal.

At the start of simulation, the block outputs the **Initial output** parameter until the simulation time exceeds the **Time delay** parameter. Then, the block begins generating the delayed input. During simulation, the block stores input points and simulation times in a buffer. You specify this size with the **Initial buffer size** parameter.

When you want output at a time that does not correspond to times of the stored input values, the block interpolates linearly between points. When the delay is smaller than the step size, the block extrapolates from the last output point, which can produce inaccurate results. Because the block does not have direct feedthrough, it cannot use the current input to calculate an output value. For example, consider a fixed-step simulation with a step size of 1 and the current time at  $t = 5$ . If the delay is 0.5, the block must generate a point at  $t = 4.5$ . Because the most recent stored time value is at  $t = 4$ , the block performs forward extrapolation.

The Transport Delay block does not interpolate discrete signals. Instead, the block returns the discrete value at the required time.

This block differs from the Unit Delay block, which delays and holds the output on sample hits only.

---

**Tip:** Avoid using `linmod` to linearize a model that contains a Transport Delay block. For more information, see “Linearizing Models” in the Simulink documentation.

---

## Data Type Support

The Transport Delay block accepts and outputs real signals of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Time delay

Specify the amount of simulation time to delay the input signal before propagation to the output.

#### Settings

**Default:** 1

This value must be nonnegative.

#### Command-Line Information

**Parameter:** DelayTime

**Type:** scalar or vector

**Value:** '1'

**Default:** '1'

## Initial output

Specify the output that the block generates until the simulation time first exceeds the time delay input.

### Settings

**Default:** Run-to-run tunable parameter

A Run-to-run tunable parameter cannot be changed during a simulation's run time. However, changing it before a simulation begins will not cause Accelerator or Rapid Accelerator to regenerate code.

Also, the initial output of this block cannot be `inf` or `NaN`.

### Command-Line Information

**Parameter:** InitialOutput

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

Controlengineers.ir

## Initial buffer size

Define the initial memory allocation for the number of input points to store.

### Settings

**Default:** 1024

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message shows the total buffer size needed.

### Tips

- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block can use a large amount of memory, particularly for dimensionalized input.

### Command-Line Information

**Parameter:** BufferSize

**Type:** scalar

**Value:** '1024'

**Default:** '1024'

## Use fixed buffer size

Specify use of a fixed-size buffer to save input data from previous time steps.

### Settings

**Default:** Off

On

The block uses a fixed-size buffer.

Off

The block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the size of the buffer. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

---

**Note:** If you have a Simulink Coder license, ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

---

### Tips

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so can yield inaccurate results.

### Command-Line Information

**Parameter:** FixedBuffer

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Direct feedthrough of input during linearization

Cause the block to output its input during linearization and trim, which sets the block mode to direct feedthrough.

### Settings

**Default:** Off

- On  
Enables direct feedthrough of input.
- Off  
Disables direct feedthrough of input.

### Tips

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:
  - 1 Compile the model using the following command, where `model` is the name of the Simulink model.
 

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```
  - 2 Terminate the compilation with the following command.
 

```
model([],[],[],'term');
```
- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

### Command-Line Information

**Parameter:** `TransDelayFeedthrough`

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Pade order (for linearization)

Set the order of the Pade approximation for linearization routines.

### Settings

**Default:** 0

- The default value is 0, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer  $n$  adds  $n$  states to your model, but results in a more accurate linear model of the transport delay.

### Command-Line Information

**Parameter:** PadeOrder

**Type:** character vector

**Value:** '0'

**Default:** '0'

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## See Also

Variable Time Delay

# Trigger

Add trigger port to model or subsystem

## Library

Ports & Subsystems

## Description

Adding a Trigger block to a model or subsystem allows an external signal to trigger its execution.

Configure the Trigger block to execute the model either:

- Once on each integration step, when the value of the external signal changes in a way that you specify.
- Multiple times during a time step, when the external signal is a function-call from a Function-Call Generator block or S-function.

Include only one Trigger block in a model or a subsystem.

Specify the properties that the trigger port enforces for any incoming signal, using the **Signal Attributes** tab.

The Trigger block supports signal label propagation.

For more information, see:

- “Triggered Subsystems”
- “Create Conditional Models”
- “Function-Call Models”

- “Function-Call Subsystems”

## Data Type Support

The Trigger block accepts signals of supported Simulink numeric data types, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

- “Trigger type” on page 1-1947
- “Treat as Simulink function” on page 1-1948
- “Function name” on page 1-1949
- “Enable variant condition” on page 1-1950
- “Variant control” on page 1-1951
- “Generate preprocessor conditionals” on page 1-1952
- “States when enabling” on page 1-1953

Controlengineers.ir

## Trigger type

Select the type of event that triggers execution of the subsystem.

### Settings

**Default:** rising

rising

Triggers execution of the model or subsystem when the control signal rises from a negative or zero value to a positive value. If the initial value is negative, rising to zero triggers execution.

falling

Triggers execution of the model or subsystem when the control signal falls from a positive or a zero value to a negative value. If the initial value is positive, falling to zero triggers execution.

either

Triggers execution of the model or subsystem when the signal is either rising or falling.

function-call

Allows a Function-Call Generator or S-function to control execution of the subsystem or model.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Treat as Simulink function

Configure the Function-Call Subsystem to be a Simulink Function block callable with arguments.

### Settings

**Default:** Off

When you select the check box, a function prototype appears on the subsystem block icon, which you can edit to configure input and output arguments to the Simulink Function.

### Tip

To use this check box to configure a subsystem as a Simulink Function block, the Trigger block must reside in the subsystem.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### Dependency

This parameter appears only when you select function-call as the **Trigger type** parameter.

Setting **Trigger type** to **function-call** and selecting the **Treat as a Simulink Function** check box enables the **Function name** and **Enable variant condition** parameters.

## Function name

Specify the function name of Simulink Function block.

### Settings

function name

This parameter provides the function name in the function prototype of the Simulink Function block.

### Dependency

Setting **Trigger type** to `function-call` and selecting the **Treat as a Simulink Function** check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Enable variant condition

Enable a variant condition on the function-call port so that the port is activated when that condition is **true**.

### Settings

**Default:** Off

When you select the check box, a variant badge  is displayed on Simulink Function, Initialize Function, Reset Function, and Terminate Function blocks indicating variant conditions are enabled.

### Dependency

Selecting this parameter enables **Variant control** and **Generate preprocessor conditionals** parameters.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Variant control

Variant control expression that activates this port when it evaluates to `true`. The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

### Dependency

Setting **Trigger type** to `function-call` and selecting the **Enable variant condition** check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Generate preprocessor conditionals

When generating code for an ERT target, this parameter determines whether variant choices are enclosed within C preprocessor conditional statements (`#if`).

### Settings

**Default:** off

### Dependency

Setting **Trigger type** to function-call and selecting the **Enable variant condition** check box enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## States when enabling

Specify the state values when triggered by a function-call.

### Settings

**Default:** held

held

Leaves the states at their current values.

reset

Resets the states.

inherit

Uses the `held/reset` setting from the parent subsystem initiating the function-call. If the parent of the initiator is the model root, the inherited setting is `held`. If the trigger has multiple initiators, set the parents of all initiators to either `held` or `reset`.

### Dependencies

To enable this parameter, select `function-call` from the **Trigger Type** list.

The parameter setting applies only if the model explicitly enables and disables the function-call subsystem. For example:

- The function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the parent subsystem.
- The function-call initiator that controls the function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the enabled subsystem containing the function-call initiator.
- The function-call initiator is a Stateflow event bound to a particular state. See “Control Function-Call Subsystems Using Bind Actions” (Stateflow) in the Stateflow documentation.
- The function-call initiator is an S-function that explicitly enables and disables the function-call subsystem. See `ssEnableSystemWithTid` for an example.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Propagate sizes of variable-size signals

Specify when to propagate a variable-size signal.

### Settings

**Default:** During execution

Only when enabling

Propagates variable-size signals only when enabling the model or subsystem containing the Trigger block.

During execution

Propagates variable-size signals at each time step.

### Dependency

Select Function-call from the **Trigger type** list to enable this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Show output port

Select this check box to output a signal that indicates the trigger type.

### Settings

**Default:** On

On

Shows the Trigger block output port and outputs the trigger type. Selecting this check box allows the system to determine which signal caused the trigger. The width of the signal is the width of the triggering signal. The signal value is:

- 1 for a signal that causes a rising trigger
- -1 for a signal that causes a falling trigger
- 2 for a function-call trigger
- 0 in all other cases

Off

Removes the output port.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Output data type

Specify the trigger output data type.

### Settings

**Default:** auto

auto

Specifies that the data type is the same as the port connected to output.

double

Sets the data type to double.

int8

Sets the data type to integer.

### Dependencies

To enable this parameter, select the **Show output port** check box.

The Trigger block ignores the **Data type override** setting of the Fixed-Point Tool.

## Sample time type

Specify the calling frequency of a subsystem.

### Settings

**Default:** triggered

triggered

Applies to applications that do not have a periodic calling frequency.

periodic

Applies if the caller of the parent function-call subsystem calls the subsystem once per time step when the subsystem is active (enabled). A Stateflow chart is an example of a caller.

### Dependency

Select Function-call from the **Trigger type** list to enable this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Sample time

Specify the calling rate for blocks.

### Settings

#### Default: 1

Set this parameter to the sample time you expect for the calling rate of the function-call subsystem containing this Trigger block. If the actual calling rate for the subsystem differs from the rate that this parameter specifies, Simulink displays an error. Set this parameter to -1 to inherit the sample time from the incoming trigger signal.

### Dependency

Setting **Trigger type** to function-call and **Sample time type** to periodic enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Enable zero-crossing detection

Select to enable zero-crossing detection.

### Settings

**Default:** On

On

Detects zero crossings.

Off

Does not detect zero crossings.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Port dimensions

Specify the dimensions of the input signal to the block.

### Settings

**Default:** 1

Valid values are:

Value	Description
n	Accepts vector signal of width n
[m n]	Accepts matrix signal having m rows and n columns

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

controlengineers.ir

## Trigger signal sample time

Specify the rate at which the block driving the triggered signal is expected to run.

### Settings

**Default:** - 1

To inherit the sample time, set this parameter to - 1.

See “Specify Sample Time” for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Minimum

Specify the minimum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Maximum

Specify the maximum value that the block should output.

### Settings

**Default:** [ ] (unspecified)

This number must be a finite real double scalar value.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Data type

Specify the expected data type of the signal feeding the trigger port.

### Settings

**Default:** Inherit: auto

Inherit: auto

Data type is double  
 double

Data type is double.  
 single

Data type is single.  
 int8

Data type is int8.  
 uint8

Data type is uint8.  
 int16

Data type is int16.  
 uint16

Data type is uint16.  
 int32

Data type is int32.  
 uint32

Data type is uint32.  
 boolean

Data type is boolean.  
 fixdt(1,16,0)

Data type is fixed point, fixdt(1,16,0).  
 fixdt(1,16,2^0,0)

Data type is fixed point, fixdt(1,16,2^0,0).  
 Enum: <class name>

Data type is enumerated, for example, Enum: Basic Colors.

<data type expression>

The name of a data type object, for example, Simulink.NumericType.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

#### Default: Inherit

##### Inherit

Inheritance rule for data types. Selecting **Inherit** enables a second list.

##### Built in

Built-in data types. Selecting **Built in** enables a second list. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

##### Fixed point

Fixed-point data types.

##### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second text box, where you can enter the class name.

##### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second text box, where you can enter the expression.

### Dependency

To enable this parameter, click **Show data type assistant**.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** Inherit

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Best precision, Binary point, Integer

#### Binary point

Specify binary point location.

#### Slope and bias

Enter slope and bias.

#### Best precision

Specify best-precision values. This option appears for some blocks.

#### Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0. This option appears for some blocks.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Interpolate data

Cause the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

### Settings

**Default:** On

On

Causes the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

Off

Does not cause the block to interpolate or extrapolate output at time steps for which no corresponding workspace data exists when loading data from the workspace.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Specified by the <b>Sample time</b> parameter if: <ul style="list-style-type: none"> <li>• <b>Trigger type</b> is function-call</li> <li>• <b>Sample time type</b> is periodic</li> </ul> Otherwise, specified by the signal at the trigger port.
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

# Trigger-Based Linearization

Generate linear models in base workspace when triggered

## Library

Model-Wide Utilities

## Description

When triggered, this block calls `linmod` or `dlinmod` to create a linear model for the system at the current operating point. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Trigger_Based_Linearization`, for example, `vdp_Trigger_Based_Linearization`. The structure has the following fields:

Field	Description
a	The A matrix of the linearization
b	The B matrix of the linearization

Field	Description
c	The C matrix of the linearization
d	The D matrix of the linearization
StateName	Names of the model's states
OutputName	Names of the model's output ports
InputName	Names of the model's input ports
OperPoint	A structure that specifies the operating point of the linearization. The structure specifies the value of the model's states ( <code>OperPoint.x</code> ) and inputs ( <code>OperPoint.u</code> ) at the operating point time ( <code>OperPoint.t</code> ).
Ts	The sample time of the linearization for a discrete linearization

Use the Timed-Based Linearization block to generate linear models at predetermined times.

You can use state and simulation time logging to extract the model states at operating points. For example, suppose that you want to get the states of the vdp example model when the signal x1 triggers the Trigger-Based Linearization block on a rising edge.

- 1 Open the model and drag an instance of this block from the Model-Wide Utilities library and drop the instance into the model.
- 2 Connect the block's trigger port to the signal labeled x1.
- 3 Open the model's **Model Configuration Parameters** dialog box.
- 4 Select the **Data Import/Export** pane.
- 5 Check **States** and **Time** on the **Save to Workspace** control panel
- 6 Select OK to confirm the selections and close the dialog box.
- 7 Simulate the model.

At the end of the simulation, the following variables appear in the MATLAB workspace: vdp\_Trigger\_Based\_Linearization, tout, and xout.

- 8 Get the index to the first operating point time by entering the following at the MATLAB command line:
 

```
ind1 = find(vdp_Trigger_Based_Linearization(1).OperPoint.t==tout);
```
- 9 Get the state vector at this operating point.

```
x1 = xout(ind1,:);
```

## Data Type Support

The trigger port accepts signals of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Trigger type

Type of event on the trigger input signal that triggers generation of a linear model. See the **Trigger type** parameter of the Trigger block for an explanation of the various trigger types that you can select.

### Sample time (of linearized model)

Specify a sample time to create a discrete-time linearization of the model (see “Discrete-Time System Linearization” on page 2-38).

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	No

## See Also

Timed-Based Linearization

Introduced before R2006a

# Triggered Subsystem

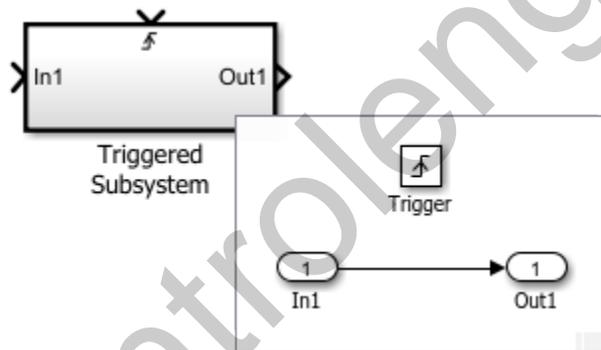

Subsystem whose execution is triggered by external input

**Library:** Ports & Subsystems

## Description

The Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes each time the control signal has a trigger event.

Use Trigger Subsystem blocks to model:

- A task that runs with the detection of an event.
- An interrupt from I/O hardware.
- A processor request to handle an exception or error.

## Ports

### Input

#### **In** — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

#### **Trigger** — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed\_point

### Output

#### **Out** — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed\_point | enumerated | bus

# Trigonometric Function

Specified trigonometric function on input

## Library

Math Operations

## Description

### Supported Functions

The Trigonometric Function block performs common trigonometric functions. You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
sin	Sine of the input	$\sin(u)$	sin
cos	Cosine of the input	$\cos(u)$	cos
tan	Tangent of the input	$\tan(u)$	tan
asin	Inverse sine of the input	$\text{asin}(u)$	asin
acos	Inverse cosine of the input	$\text{acos}(u)$	acos
atan	Inverse tangent of the input	$\text{atan}(u)$	atan
atan2	Four-quadrant inverse tangent of the input	$\text{atan2}(u)$	atan2

Function	Description	Mathematical Expression	MATLAB Equivalent
sinh	Hyperbolic sine of the input	$\sinh(u)$	sinh
cosh	Hyperbolic cosine of the input	$\cosh(u)$	cosh
tanh	Hyperbolic tangent of the input	$\tanh(u)$	tanh
asinh	Inverse hyperbolic sine of the input	$\operatorname{asinh}(u)$	asinh
acosh	Inverse hyperbolic cosine of the input	$\operatorname{acosh}(u)$	acosh
atanh	Inverse hyperbolic tangent of the input	$\operatorname{atanh}(u)$	atanh
sincos	Sine of the input; cosine of the input	—	—
cos + j sin	Complex exponential of the input	—	—

The block output is the result of applying the function to one or more inputs in radians. Each function supports:

- Scalar operations
- Element-wise vector and matrix operations

---

**Note:** Not all compilers support the `asinh`, `acosh`, and `atanh` functions. If you use a compiler that does not support those functions, a warning appears and the generated code fails to link.

---

## Block Appearance for the atan2 Function

If you select the `atan2` function, the block shows two inputs. The first input is the  $y$ -axis or imaginary part of the function argument. The second input is the  $x$ -axis or real part of the function argument. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.)

## Block Appearance for the sincos Function

If you select the `sincos` function, the block shows two outputs. The first output is the sine of the function argument, and the second output is the cosine of the function argument.

## Definitions

### CORDIC

CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

## Data Type Support

The block accepts input signals of the following data types:

Functions	Input Data Types
<ul style="list-style-type: none"> <li>• <code>sin</code></li> <li>• <code>cos</code></li> <li>• <code>sincos</code></li> <li>• <code>cos + jsin</code></li> <li>• <code>atan2</code></li> </ul>	<ul style="list-style-type: none"> <li>• Floating point</li> <li>• Fixed point (only when <b>Approximation method</b> is CORDIC)</li> </ul>
<ul style="list-style-type: none"> <li>• <code>tan</code></li> <li>• <code>asin</code></li> <li>• <code>acos</code></li> </ul>	<ul style="list-style-type: none"> <li>• Floating point</li> </ul>

Functions	Input Data Types
<ul style="list-style-type: none"> <li>• atan</li> <li>• sinh</li> <li>• cosh</li> <li>• tanh</li> <li>• asinh</li> <li>• acosh</li> <li>• atanh</li> </ul>	

Complex input signals are supported for all functions in this block, except atan2.

Controlengineers.ir

You can use floating-point input signals when you set **Approximation method** to **None** or **CORDIC**. However, the block output data type depends on which of these approximation method options you choose.

Input Data Type	Approximation Method	Output Data Type
Floating point	None	Depends on your selection for <b>Output signal type</b> . Options are <b>auto</b> (same data type as input), <b>real</b> , or <b>complex</b> .
Floating point	CORDIC	Same as input. <b>Output signal type</b> is not available when you use the CORDIC approximation method to compute the block output.

You can use fixed-point input signals only when **Approximation method** is set to **CORDIC**. The CORDIC approximation is available for the **sin**, **cos**, **sincos**, **cos + jsin**, and **atan2** functions. For the **atan2** function, the relationship between input and output data types depends also on whether the fixed-point input is signed or unsigned.

Input Data Type	Function	Output Data Type
Fixed point, signed or unsigned	<b>sin</b> , <b>cos</b> , <b>sincos</b> , and <b>cos + jsin</b>	<b>fixdt(1, WL, WL - 2)</b> where <b>WL</b> is the input word length  This fixed-point type provides the best precision for the CORDIC algorithm.
Fixed point, signed	<b>atan2</b>	<b>fixdt(1, WL, WL - 3)</b>
Fixed point, unsigned	<b>atan2</b>	<b>fixdt(1, WL, WL - 2)</b>

For CORDIC approximations:

- Input must be real for the `sin`, `cos`, `sincos`, `cos + jsin`, and `atan2` functions.
- Output is real for the `sin`, `cos`, `sincos`, and `atan2` functions.
- Output is complex for the `cos + jsin` function.

## Invalid Inputs for CORDIC Approximations

If you use the CORDIC approximation method (see “Definitions” on page 1-1986), the block input has some further requirements.

For the `sin`, `cos`, `sincos`, and `cos + jsin` functions:

- When you use signed fixed-point types, the input angle must fall within the range  $[-2\pi, 2\pi)$  radians.
- When you use unsigned fixed-point types, the input angle must fall within the range  $[0, 2\pi)$  radians.

For the `atan2` function:

- Inputs must be the same size, or at least one value must be a scalar value.
- Both inputs must have the same data type.
- When you use signed fixed-point types, the word length must be **126** or less.
- When you use unsigned fixed-point types, the word length must be **125** or less.

This table summarizes what happens for an invalid input.

Block Usage	Effect of Invalid Input
Simulation	An error appears.
Generated code	Undefined behavior occurs. Avoid relying on undefined behavior for generated code or Accelerator modes.
Accelerator modes	

## Parameters

### Function

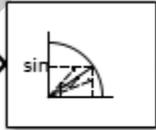

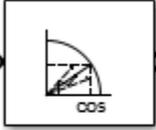

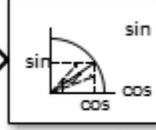

Specify the trigonometric function. The name of the function on the block icon changes to match your selection.

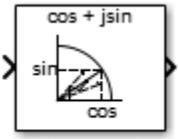

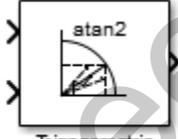

**Approximation method**

Specify the type of approximation for computing output. This parameter appears only when you set **Function** to **sin**, **cos**, **sincos**, **cos + jsin**, or **atan2**.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

If you select **CORDIC** and enlarge the block from the default size, the block icon changes:

Function	Block Icon
sin	 <p>Trigonometric Function</p>
cos	 <p>Trigonometric Function</p>
sincos	 <p>Trigonometric Function</p>

Function	Block Icon
cos + jsin	 <p>Trigonometric Function</p>
atan2	 <p>Trigonometric Function</p>

### Number of iterations

Specify the number of iterations to perform the CORDIC algorithm. The default value is 11.

- When the block input uses a floating-point data type, the number of iterations can be a positive integer.
- When the block input is a fixed-point data type, the number of iterations cannot exceed the word length.

For example, if the block input is `fixdt(1, 16, 15)`, the word length is 16. In this case, the number of iterations cannot exceed 16.

This parameter appears when both of the following conditions hold:

- You set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- You set **Approximation method** to `CORDIC`.

### Output signal type

Specify the output signal type of the Trigonometric Function block as `auto`, `real`, or `complex`.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
Any selection for the <b>Function</b> parameter	real	real	real	complex
	complex	complex	error	complex

**Note:** When **Function** is `atan2`, complex input signals are not supported for simulation or code generation.

Setting **Approximation method** to CORDIC disables this parameter.

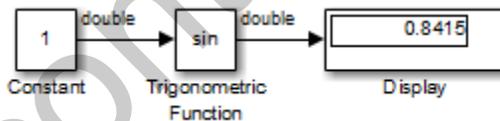

### Sample time

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

## Examples

### sin Function with Floating-Point Input

Suppose that you have the following model:

The key block parameters for the Constant block are:

Parameter	Setting
Constant value	1

Parameter	Setting
Output data type	Inherit: Inherit from 'Constant value'

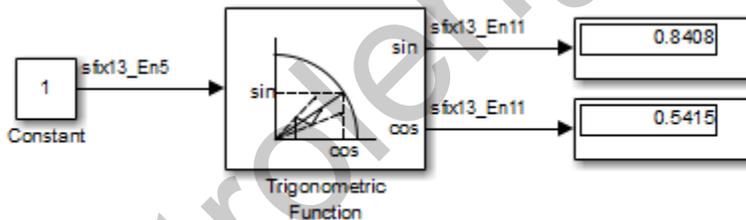

The block parameters for the Trigonometric Function block are:

Parameter	Setting
Function	sin
Approximation method	None
Output signal type	auto

The output type of the Trigonometric Function block is the same as the input because the input type is floating point and **Approximation method** is None.

### sincos Function with Fixed-Point Input

Suppose that you have the following model:

The key block parameters for the Constant block are:

Parameter	Setting
Constant value	1  This value must fall within the range $[-2\pi, 2\pi]$ because the Trigonometric Function block uses the CORDIC algorithm and the block input uses a signed fixed-point type.
Output data type	fixdt(1, 13, 5)

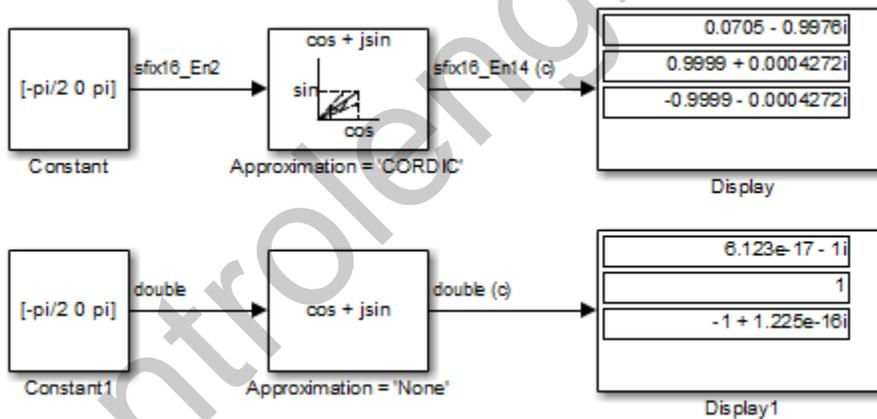

The block parameters for the Trigonometric Function block are:

Parameter	Setting
Function	sincos
Approximation method	CORDIC
Number of iterations	11

The output type of the Trigonometric Function block is `fixdt(1,13,11)` because the input type is fixed point and **Approximation method** is CORDIC. The output fraction length equals the input word length – 2.

### Block Behavior for Complex Exponential Output

The following model compares the complex exponential output for the two different approximation methods:

The key block parameters for the Constant blocks are:

Block	Parameter	Setting
Constant	Constant value	$[-\pi/2 \ 0 \ \pi]$
	Output data type	<code>fixdt(1,16,2)</code>
Constant1	Constant value	$[-\pi/2 \ 0 \ \pi]$

Block	Parameter	Setting
	Output data type	double

The block parameters for the Trigonometric Function blocks are:

Block	Parameter	Setting
Approximation = 'CORDIC'	Function	cos + jsin
	Approximation method	CORDIC
	Number of iterations	11
Approximation = 'None'	Function	cos + jsin
	Approximation method	None

When the **Approximation method** is CORDIC, the input data type can be fixed point, in this case: `fixdt(1,16,2)`. The output data type is `fixdt(1,16,14)` because the output fraction length equals the input word length – 2.

When the **Approximation method** is None, the input data type must be floating point. The output data type is the same as the input.

## Characteristics

Data Types	Double   Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# Unary Minus

Negate input

## Library

Math Operations

## Description

The Unary Minus block negates the input.

For signed-integer data types, the unary minus of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block:

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> <li>For 8-bit signed integers, -128 maps to 127.</li> <li>For 16-bit signed integers, -32768 maps to 32767.</li> <li>For 32-bit signed integers, -2147483648 maps to 2147483647.</li> </ul>
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> <li>For 8-bit signed integers, -128 remains -128.</li> <li>For 16-bit signed integers, -32768 remains -32768.</li> <li>For 32-bit signed integers, -2147483648 remains -2147483648.</li> </ul>

## Data Type Support

The Unary Minus block accepts and outputs signals of the following data types:

- Floating point
- Signed integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Sample time

---

**Note:** This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

---

### Saturate on integer overflow

Select to have integer overflows saturate. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes

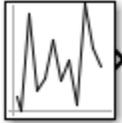

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

# Uniform Random Number

Generate uniformly distributed random numbers

## Library

Sources

## Description

The Uniform Random Number block generates uniformly distributed random numbers over an interval that you specify. To generate normally distributed random numbers, use the Random Number block.

You can generate a repeatable sequence using any Uniform Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

## Data Type Support

The Uniform Random Number block accepts and outputs a real signal of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Minimum

Specify the minimum of the interval. The default is - 1.

### Maximum

Specify the maximum of the interval. The default is 1.

### Seed

Specify the starting seed for the random number generator. The default is 0.

The seed must be 0 or a positive integer. Output is repeatable for a given seed.

### Sample time

Specify the time interval between samples. The default is 0.1. See “Specify Sample Time” in the Simulink documentation for more information.

### Interpret vector parameters as 1-D

If you select this check box and the other parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. Otherwise, the block outputs a signal of the same dimensionality as the other parameters. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

## Characteristics

Data Types	Double
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

The generator algorithm is identical to the one used in MATLAB Version 4.0 by the `rand` and `randn` functions. For details on the `mcg16807` algorithm, see “Choosing a Random Number Generator” (MATLAB) in the MATLAB documentation.

To use other algorithms supported by MATLAB in a Simulink model, generate a set of random numbers in MATLAB, and store the output as a `.mat` file. Use this `.mat` file as the random number input for your simulation. For more information, see “Creating and Controlling a Random Number Stream” (MATLAB). To create multiple independent streams using MATLAB, see “Multiple Streams” (MATLAB)

---

**Note:** Using multiple seeds to generate multiple parallel independent streams for a generator algorithm is not recommended for the `mcg16807` algorithm. Instead, use the method described above.

# Unit System Configuration

Configure units

## Library

Ports & Subsystems

## Description

The Unit System Configuration block specifies allowed and disallowed unit systems for the component. It restricts units systems for a subsystem or top model and all its children, unless you override it with another Unit System Configuration block in a child.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

## Parameters

### Disallowed unit systems

Displays disallowed unit system.

To designate a unit system as disallowed, select it in the **Allowed unit systems** column and click <<**Disallow**.

### Settings

**Default:** None

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Allowed unit systems

Displays allowed unit system.

To designate a unit system as allowed, select it in the **Disallowed unit systems** column and click **Allow**>>.

### Settings

**Default:** SI, English, SI (extended), CGS

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Allow all unit systems

Allow or restrict unit systems.

### Settings

**Default:** On

On

Allow all unit systems.

Off

Restrict unit systems to those in **Allowed unit systems**.

### Dependencies

Selecting the **Allow all unit systems** check box disables the **Disallowed unit systems** and **Allowed unit systems** parameters.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Unit Conversion

Convert units

### Library

Signal Attributes

### Description

The Unit Conversion block converts the unit of the input signal to the output signal. The block can convert if the units are separated by a scaling factor or offset, or are inverse units, for example:

- $y=a*U$
- $y=a*U+b$ , where  $a$  is the scale and  $b$  is the offset
- $y=a/U$

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

### Data Type Support

The Unit Conversion block accepts and outputs real or complex values of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Output data type

Specify the output data type.

#### Settings

**Default:** Inherit: Inherit via internal rule

**Inherit:** Inherit via internal rule

Simulink chooses intermediate and output data types to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change.

**Inherit:** Inherit via back propagation

Output data type is inherited via back propagation. Internal rules determine the intermediate data types and Simulink casts the final results to the output data type.

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

#### See Also

See “Converting Units” for more information.

## Characteristics

Data Types	Double   Single   Base Integer   Fixed-Point

# Unit Delay

Delay signal one sample period

## Library

Discrete

## Description

The Unit Delay block holds and delays its input by the sample period you specify. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block is equivalent to the  $z^{-1}$  discrete-time operator. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds and delays all elements of the vector by the same sample period.

You specify the block output for the first sampling period with the **Initial conditions** parameter. Careful selection of this parameter can minimize unwanted output behavior. You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

---

**Note:** The Unit Delay block errors out if you use it to create a transition between blocks operating at different sample rates. Use the **Rate Transition** block instead.

---

## Comparison with Similar Blocks

### Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

### Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_enginewc (Compression subsystem)</li> </ul>
Memory on page 1-1003	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> <li>• sldemo_bounce</li> <li>• sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)</li> </ul>
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_radar_em1</li> <li>• aero_dap3dof</li> </ul>

### Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of sample time	Yes	No, because the block can only inherit sample time (from the driving block or the solver used for the entire model).	Yes
Support for frame-based signals	Yes	No	Yes
Support for state logging	Yes	No	No

## Data Type Support

The Unit Delay block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. If the data type of the input signal is user-defined, the initial condition must be zero.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

## Initial conditions

Specify the output of the simulation for the first sampling period, during which the output of the Unit Delay block is otherwise undefined.

### Settings

**Default:** 0

The **Initial conditions** parameter is converted from a double to the input data type offline using round-to-nearest and saturation.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Input processing

Specify whether the Unit Delay block performs sample- or frame-based processing.

### Settings

**Default:** Elements as channels (sample based)

Elements as channels (sample based)

Treat each element of the input as a separate channel (sample-based processing).

Columns as channels (frame based)

Treat each column of the input as a separate channel (frame-based processing).

Inherited

Sets the block to inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

---

**Note:** When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink® will generate a warning or error in future releases.

---

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input **u**. All other input signals must be sample based.

Input Signal <b>u</b>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

### **Dependency**

Frame-based processing requires a DSP System Toolbox license.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Sample time (-1 for inherited)

Enter the discrete interval between sample time hits or specify -1 to inherit the sample time.

### Settings

**Default:** -1

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

See also “Specify Sample Time” in the online documentation for more information.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## State name

Use this parameter to assign a unique name to each state.

### Settings

**Default:** ' '

- If left blank, no name is assigned.

### Tips

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

### Dependency

This parameter enables **State name must resolve to Simulink signal object** when you click the **Apply** button.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

### Command-Line Information

**Parameter:** StateIdentifier

**Type:** character vector

**Value:** ' '

**Default:** ' '

## State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

### Settings

**Default:** Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

### Dependencies

**State name** enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

### Command-Line Information

**Parameter:** StateMustResolveToSignalObject

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

To programmatically set this parameter, use `StateSignalObject`.

For examples and more information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

### Settings

#### `Simulink.Signal`

Use custom storage classes from the built-in package `Simulink`.

#### `Package.Class`

Use custom storage classes from the package that defines the class that you select.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

## Code generation storage class

Select state storage class for code generation.

### Settings

**Default:** Auto

#### Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

#### *StorageClass*

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

### Dependencies

**State name** enables this parameter.

## TypeQualifier

---

**Note:** `TypeQualifier` will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

---

Specify a storage type qualifier such as `const` or `volatile`.

### Settings

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

### Dependency

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

### Command-Line Information

**Parameter Name:** `RTWStateStorageTypeQualifier`

**Value Type:** character vector

**Default:** ' ' (empty character vector)

## Bus Support

The Unit Delay block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial conditions** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial conditions** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial conditions** is a nonzero scalar, no **State name** can be specified.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Unit Delay block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and **Bus-Capable Blocks** for more information.

You can use an array of buses as an input signal to a Unit Delay block. You can specify the **Initial conditions** parameter with:

- The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Examples

For an example of how to use the Unit Delay block, see the `sldemo_enginewc` model. The Unit Delay block appears in the **Compression** subsystem.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

# Variable Time Delay, Variable Transport Delay

Delay input by variable amount of time

## Library

Continuous

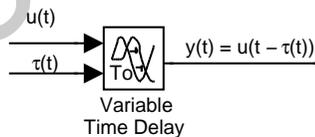

## Description

The Variable Transport Delay and Variable Time Delay appear as two blocks in the Simulink block library. However, they are the same Simulink block with different settings of a **Select delay type** parameter. Use this parameter to specify the mode in which the block operates.

## Variable Time Delay

In this mode, the block has a data input, a time delay input, and a data output. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.) The output at the current time step equals the value of its data input at a previous time step. This time step is the current simulation time minus a delay time specified by the time delay input.

$$y(t) = u(t - t_0) = u(t - \tau(t))$$

During the simulation, the block stores time and input value pairs in an internal buffer. At the start of simulation, the block outputs the value of the **Initial output** parameter until the simulation time exceeds the time delay input. Then, at each simulation step, the block outputs the signal at the time that corresponds to the current simulation time minus the delay time.

If you want the output at a time between input storing times and the solver is a continuous solver, the block interpolates linearly between points. If the time delay is smaller than the step size, the block extrapolates an output point from a previous point. For example, consider a fixed-step simulation with a step size of 1 and the current time at  $t = 5$ . If the delay is 0.5, the block needs to generate a point at  $t = 4.5$ , but the most recent stored time value is at  $t = 4$ . Thus, the block extrapolates the input at 4.5 from the input at 4 and uses the extrapolated value as its output at  $t = 5$ .

Extrapolating forward from the previous time step can produce a less accurate result than extrapolating back from the current time step. However, the block cannot use the current input to calculate its output value because the input port does not have direct feedthrough.

If the model specifies a discrete solver, the block does not interpolate between time steps. Instead, it returns the nearest stored value that precedes the required value.

## Variable Transport Delay

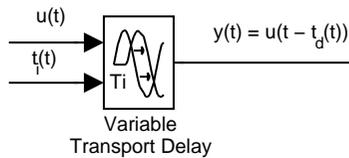

In this mode, the block output at the current time step is equal to the value of its data (top, or left) input at an earlier time step equal to the current time minus a transportation delay.

$$y(t) = u(t - t_d(t))$$

Simulink software finds the transportation delay,  $t_d(t)$ , by solving the following equation:

$$\int_{t-t_d(t)}^t \frac{1}{t_i(\tau)} d\tau = 1$$

This equation involves an instantaneous time delay,  $t_i(t)$ , given by the time delay (bottom, or right) input.

Suppose you want to use this block to model the fluid flow through a pipe where the fluid speed varies with time. In this case, the time delay input to the block is

$$t_i(t) = \frac{L}{v_i(t)}$$

where  $L$  is the length of the pipe and  $v_i(t)$  is the speed of the fluid.

## Data Type Support

The Variable Time Delay and Variable Transport Delay blocks accept and output real signals of type **double**.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Select delay type

Specify the mode in which the block operates.

#### Settings

**Default:** The Variable Time Delay block has a default value of **Variable time delay**. The Variable Transport Delay block has a default value of **Variable transport delay**.

#### Variable time delay

Specifies a Variable Time Delay block.

## Variable transport delay

Specifies a Variable Transport Delay block.

### Dependencies

Setting this parameter to `Variable time delay` enables the **Handle zero delay** parameter.

Setting this parameter to `Variable transport delay` enables the **Absolute tolerance** and **State Name** parameters.

### Command-Line Information

**Parameter:** VariableDelayType

**Type:** character vector

**Value:** 'Variable transport delay' | 'Variable time delay'

**Default:** 'Variable time delay'

Controlengineers.ir

## Maximum delay

Set the maximum value of the time delay input.

### Settings

**Default:** 10

- This value defines the largest time delay input that this block allows. The block clips any delay that exceeds this value.
- This value cannot be negative. If the time delay becomes negative, the block clips it to zero and issues a warning message.

### Command-Line Information

**Parameter:** MaximumDelay

**Type:** scalar or vector

**Value:** '10'

**Default:** '10'

## Initial output

Specify the output that the block generates until the simulation time first exceeds the time delay input.

### Settings

**Default:** Run-to-run tunable parameter

A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins will not cause Accelerator or Rapid Accelerator to regenerate code. Also, the initial output of this block cannot be `inf` or `NaN`.

### Command-Line Information

**Parameter:** InitialOutput

**Type:** scalar or vector

**Value:** '0'

**Default:** '0'

Controlengineers.ir

## Initial buffer size

Define the initial memory allocation for the number of input points to store. The input points define the history of the input signal up to the current simulation time.

### Settings

**Default:** 1024

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message displays if the buffer is not sufficient and more memory needs to be allocated.

### Tips

- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block might use a large amount of memory, particularly for dimensionalized input.

### Command-Line Information

**Parameter:** MaximumPoints

**Type:** scalar

**Value:** '1024'

**Default:** '1024'

## Use fixed buffer size

Specify use of a fixed-size buffer to save input data from previous time steps.

### Settings

**Default:** Off

On

The block uses a fixed-size buffer.

Off

The block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the buffer size. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

---

**Note:** ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

---

### Tips

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so might yield inaccurate results.

### Command-Line Information

**Parameter:** FixedBuffer

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Handle zero delay

Convert this block to a direct feedthrough block.

### Settings

**Default:** Off

On

The block uses direct feedthrough.

Off

The block does not use direct feedthrough.

### Dependency

Setting **Select delay type** to **Variable time delay** enables this parameter.

### Command-Line Information

**Parameter:** ZeroDelay

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Direct feedthrough of input during linearization

Cause the block to output its input during linearization and trim, which sets the block mode to direct feedthrough.

### Settings

**Default:** Off

- On  
Enables direct feedthrough of input.
- Off  
Disables direct feedthrough of input.

### Tips

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:
  - 1 Compile the model using the following command, where `model` is the name of the Simulink model.
 

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```
  - 2 Terminate the compilation with the following command.
 

```
model([],[],[],'term');
```
- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

### Command-Line Information

**Parameter:** `TransDelayFeedthrough`

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Pade order (for linearization)

Set the order of the Pade approximation for linearization routines.

### Settings

**Default:** 0

- The default value is 0, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer  $n$  adds  $n$  states to your model, but results in a more accurate linear model of the transport delay.

### Command-Line Information

**Parameter:** PadeOrder

**Type:** character vector

**Value:** '0'

**Default:** '0'

## Absolute tolerance

Specify the absolute tolerance for computing the block state.

**Default:** auto

- You can enter `auto`, `-1`, or a positive real scalar or vector.
- If you enter `auto`, or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

### Dependency

Setting **Select delay type** to **Variable transport delay** enables this parameter.

### Command-Line Information

**Parameter:** AbsoluteTolerance

**Type:** character vector, scalar, or vector

**Value:** 'auto' | '-1' | any positive real scalar or vector

**Default:** 'auto'

### State Name (e.g., 'position')

Assign a unique name to each state.

### Settings

**Default:** ''

If this field is blank, no name assignment occurs.

### Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.

- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

### Dependency

Setting **Select delay type** to **Variable transport delay** enables this parameter.

### Command-Line Information

**Parameter:** ContinuousStateAttributes

**Type:** character vector

**Value:** ' ' | user-defined

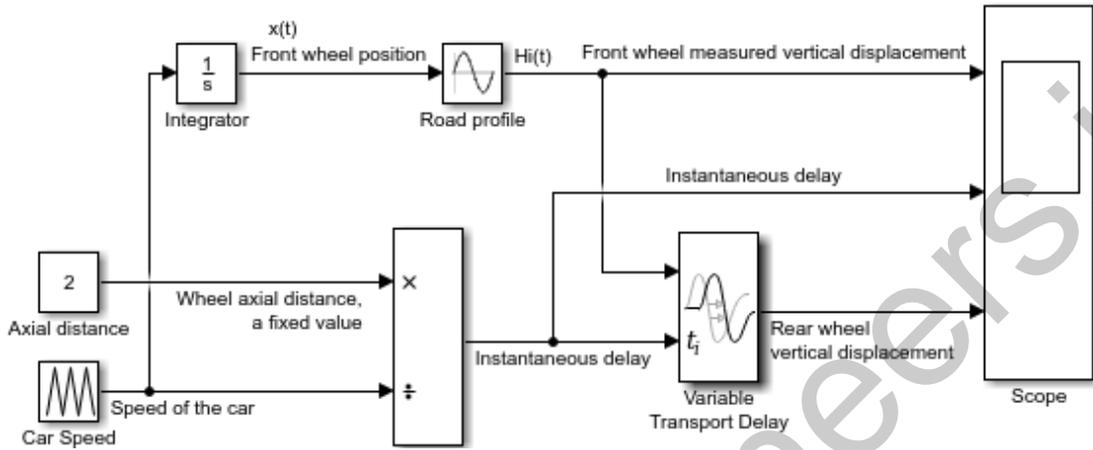

**Default:** ' '

## Examples

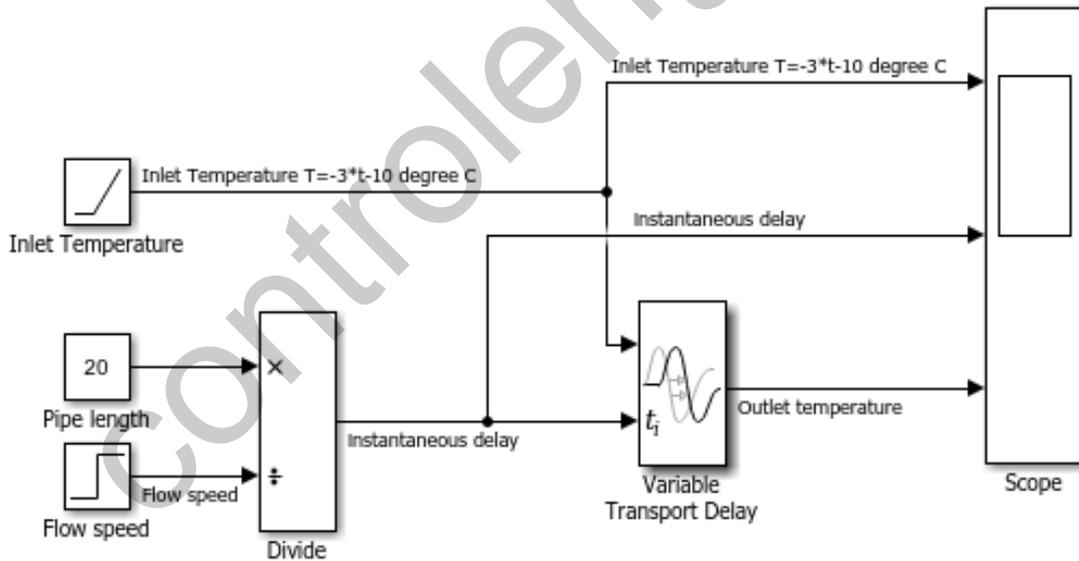

The `sldemo_VariableTransportDelay` and `sldemo_VariableTransportDelay_pipe` models show how you can use the Variable Transport Delay block.

The `sldemo_VariableTransportDelay` model shows how to model vertical wheel displacement on a one-dimensional car. The Variable Transport Delay block models the delay in vertical displacement of the rear wheel when the road profile changes:

1 Blocks – Alphabetical List

The `sldemo_VariableTransportDelay_pipe` model shows how to model incompressible flow through a fixed-length pipe. The Variable Transport Delay block models the delay in temperature change at the outlet when fluid flow occurs:

## Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Yes, of the time delay (second) input
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

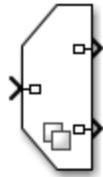

## See Also

Transport Delay

Introduced in R2007a

## Variant Sink

Route amongst multiple outputs using variants

### Library

Signal Routing

### Description

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active.

Each output port is associated with a variant control. The variant control that evaluates to `true`, determines which output port is active.

During simulation, Simulink connects the active choice directly to the input port of the Variant Sink block and ignores the inactive choices.

### Parameters

#### Ports and associated conditions

A table of port choices, variant controls, and conditions. The **Variant control** that evaluates to `true` determines which input port must be active.

## Settings

**Default:** The table has a row for each variant choice exiting in the Variant Sink block. See each column parameter for its default value:

- “Port” on page 1-2041
- “Variant Control” on page 1-2042
- “Condition (read-only)” on page 1-2043

## See Also

- “Define, Configure, and Activate Variants”
- “Introduction to Variant Controls”

## Port

Number of the input port that is connected to one variant choice upstream of the Variant Sink block

## Settings

A read-only field, based on the input port that is connected to one variant choice upstream of the Variant Sink block.

Click  to add a port or  to delete an existing one.

## Variant Control

Displays the variant controls available in the base workspace. The variant control can be a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression. Click **Apply** after you edit a variant control name. If you add or delete a variant control without applying the changes, the previous edits on the variant control name are lost.

### Command-Line Information

**Parameter:** VariantControls

**Type:** cell array of character vectors

**Value:** Variant control that is associated with the variant choice.

**Default:** ''

## Condition (read-only)

Displays the **Condition** for the variant controls that are `Simulink.Variant` objects.

### Settings

A read-only field, based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

### See Also

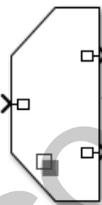

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

## Override variant conditions and use the following variant

Ignores the variant control value while determining the active variant and uses the overridden variant control as the active variant. The overriding variant control must be defined in the variant block dialog box.

If you do not select this option, Simulink determines the active variant choice based on the variant control that evaluates to `true` in the global workspace.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Off

On

Use the specified variant instead of selecting the active variant from the variant control.

Off

Determine the active variant choice based on the variant control that evaluates to true.

### Dependencies

This parameter enables **Variant**.

### Command-Line Information

**Parameter:** OverrideUsingVariant

**Type:** character vector

**Value:** '' if no overriding variant is specified.

**Default:** ''

### See Also

- “Working with Variant Choices”

## Variant

Select the variant control that Simulink uses if you select **Override variant conditions and use the following variant**.

### Settings

**Default:** ''

The **Variant** drop-down list displays all variant controls that are currently defined in the base workspace or a data dictionary. Use valid MATLAB identifiers to specify variant controls.

### Dependencies

**Override variant conditions and use the following variant** enables this parameter.

### Command-Line Information

**Parameter:** OverrideUsingVariant

**Type:** character vector

**Value:** Specified by the variant control expression.

### See Also

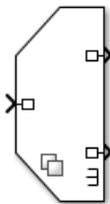

- Simulink.Variant

## Allow zero active variant controls

To simulate a model (containing a variant block) without an active variant choice, select the **Allow zero active variant controls** option. When this option is selected and there is no active variant choice, Simulink disables all the blocks connected to the input and output stream of Variant Sink block. The removed blocks are ignored from update diagram or simulation.

If you do not select this option, Simulink generates an error when there is no active variant choice.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Command-Line Information

**Parameter:** AllowZeroVariantControls

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Show variant condition on block

When you select this option, Simulink annotates each variant control (condition expression) on the Variant Sink block ports.

### Settings

**Default:** Disabled

### Command-Line Information

**Parameter:** ShowConditionOnBlock

**Type:** character vector

**Value:** 'off' | 'on'

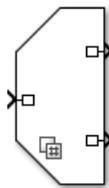

**Default:** 'off'

## Analyze all choices during update diagram and generate preprocessor conditionals

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis helps Simulink to maintain consistency of all variant branches during simulation and code generation. Simulink routes the output of the active and inactive regions to an internal VariantMerge block.

When this option is selected, the preprocessor conditionals (`#if`) are generated in the code with ERT-based targets.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Dependencies

- The check box is available for generating ERT targets only.
- **Override variant conditions and use following variant** is cleared ('off')

### Command-Line Information

**Parameter:** GeneratePreprocessorConditionals

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

**Introduced in R2016a**

## Variant Source

Route amongst multiple inputs using variants

### Library

Signal Routing

### Description

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active.

Each input port is associated with a variant control. The variant control that evaluates to `true`, determines which input port is active.

During simulation, Simulink connects the active choice directly to the output port of the Variant Source block and ignores the inactive choices.

### Parameters

#### Ports and associated conditions

A table of port choices, variant controls, and conditions. The **Variant control** that evaluates to `true` determines which input port must be active.

## Settings

**Default:** The table has a row for each variant choice feeding into the Variant Source block. See each column parameter for its default value:

- “Port” on page 1-2049
- “Variant Control” on page 1-2050
- “Condition (read-only)” on page 1-2051

## See Also

- “Define, Configure, and Activate Variants”
- “Introduction to Variant Controls”

## Port

Number of the input port that is connected to one variant choice upstream of the Variant Source block

## Settings

A read-only field, based on the input port that is connected to one variant choice upstream of the Variant Source block.

Click  to add a port or  to delete an existing one.

## Variant Control

Displays the variant controls available in the base workspace. The variant control can be a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression. Click **Apply** after you edit a variant control name. If you add or delete a variant control without applying the changes, the previous edits on the variant control name are lost.

### Command-Line Information

**Parameter:** VariantControls

**Type:** cell array of character vectors

**Value:** Variant control that is associated with the variant choice.

**Default:** ''

## Condition (read-only)

Displays the **Condition** for the variant controls that are `Simulink.Variant` objects.

### Settings

A read-only field, based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

### See Also

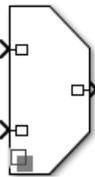

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

## Override variant conditions and use the following variant

Ignores the variant control value while determining the active variant and uses the overridden variant control as the active variant. The overriding variant control must be defined in the variant block dialog box.

If you do not select this option, Simulink determines the active variant choice based on the variant control that evaluates to `true` in the global workspace.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Off

On

Use the specified variant instead of selecting the active variant from the variant control.

Off

Determine the active variant choice based on the variant control that evaluates to true.

### Dependencies

This parameter enables **Variant**.

### Command-Line Information

**Parameter:** OverrideUsingVariant

**Type:** character vector

**Value:** ' ' if no overriding variant is specified.

**Default:** ' '

### See Also

- “Working with Variant Choices”

### Variant

Select the variant control that Simulink uses if you select **Override variant conditions and use the following variant**.

### Settings

**Default:** ' '

The **Variant** drop-down list displays all variant controls that are currently defined in the base workspace or a data dictionary. Use valid MATLAB identifiers to specify variant controls.

### Dependencies

**Override variant conditions and use the following variant** enables this parameter.

### Command-Line Information

**Parameter:** OverrideUsingVariant

**Type:** character vector

**Value:** Specified by the variant control expression.

### See Also

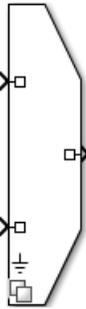

- Simulink.Variant

## Allow zero active variant controls

To simulate a model (containing a variant block) without an active variant choice, select the **Allow zero active variant controls** option. When this option is selected and there is no active variant choice, Simulink disables all the blocks connected to the input and output stream of Variant Source block. The removed blocks are ignored from update diagram or simulation.

If you do not select this option, Simulink generates an error when there is no active variant choice.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Command-Line Information

**Parameter:** AllowZeroVariantControls

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Show variant condition on block

When you select this option, Simulink annotates each variant control (condition expression) on the Variant Source block ports.

### Settings

**Default:** Disabled

### Command-Line Information

**Parameter:** ShowConditionOnBlock

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

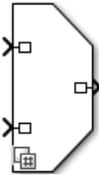

## Analyze all choices during update diagram and generate preprocessor conditionals

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis helps Simulink to maintain consistency of all variant branches during simulation and code generation. Simulink routes the output of the active and inactive regions to an internal `VariantMerge` block.

When this option is selected, the preprocessor conditionals (`#if`) are generated in the code with ERT-based targets.

If this option is selected during code generation, the data type and the semantics at all input ports of the Variant Source block must be same to avoid failure.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Dependencies

- The check box is available for generating ERT targets only.
- **Override variant conditions and use following variant** is cleared ('off')

### Command-Line Information

**Parameter:** GeneratePreprocessorConditionals

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

**Introduced in R2016a**

## Variant Subsystem

Represent multiple implementations of a system via a subsystem

## Library

Ports & Subsystems

## Description

The Variant Subsystem block can have one active choice for simulation. The variant control determines which choice is active. The variant control can be a condition expression, a `Simulink.Variant` object specifying a condition expression or a default variant.

The Variant Subsystem block can include Inport, Outport, and Connection Port blocks. There are no drawn connections inside the Variant Subsystem block. Each child subsystem is associated with a variant control, which is created in the base workspace. The variant control that evaluates to `true`, determines the active variant.

## Data Type Support

For information on the data types accepted by a subsystem input ports, see `Inport` block. For information on data types output by a subsystem output ports, see `Outport` block.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Mapping Inports and Outports

Each subsystem block within a Variant Subsystem represents one variant configuration. These subsystem blocks can have different numbers of inports and outports than their parent variant subsystem, provided the following conditions are satisfied.

- The inport names on a variant are a subset of the inport names used by the parent variant subsystem.
- The outport names on a variant are a subset of the outport names used by the parent variant subsystem.

During simulation, Simulink disables the inactive ports in a variant subsystem block.

## Parameter

- “Variant choices (list of child subsystems)” on page 1-2057
- “Name (read-only)” on page 1-2059
- “Variant Control” on page 1-2060
- “Condition (read-only)” on page 1-2061
- “Override variant conditions and use following variant” on page 1-2062
- “Variant” on page 1-2063
- “Analyze all choices during update diagram and generate preprocessor conditionals” on page 1-2064
- “Propagate conditions outside of variant subsystem” on page 1-2064

## Variant choices (list of child subsystems)

Displays a table of variant choices, variant control, and conditions. The Variant control that evaluates to true determines the active variant.

### Settings

**Default:** The table has a row for each subsystem in the Variant Subsystem block. If the Variant Subsystem block does not contain any subsystems, then the table is empty. See each column parameter for its default value:

- “Name (read-only)” on page 1-2059

- “Variant Control” on page 1-2060
- “Condition (read-only)” on page 1-2061

**Tip**

You can use buttons to the left of the **Variant choices** table to modify the elements in the table.

To...	Click...
<b>Create and add a new subsystem choice:</b> Places a new subsystem choice in the table and creates a new subsystem block in the Variant Subsystem block diagram.	
<b>Create and add a new model variant choice:</b> Places a new model choice in the table and creates a model block in the Variant Subsystem block diagram.	
<b>Create/Edit selected variant object:</b> Creates a Simulink.Variant object in the base workspace and opens the Simulink.Variant object parameter dialog box to specify the variant <b>Condition</b> .	
<b>Open selected variant choice block:</b> Opens the subsystem block diagram for the selected row in the <b>Variant choices</b> table.	
<b>Refresh dialog information from variant subsystem contents:</b> Updates the <b>Variant choices</b> table according to the Subsystem block configuration and values of the variant control in the base workspace.	

**See Also**

- “Define, Configure, and Activate Variants”
- “Introduction to Variant Controls”

## Name (read-only)

Name of the subsystem or model variant choice (contained in the Variant Subsystem block)

### Settings

A read-only field, based on the subsystem or model variant choice contained in the Variant Subsystem block.

Click  to add a subsystem variant choice or  to add a model variant choice to the Variant Subsystem block.

Controlengineers.ir

## Variant Control

Displays the variant controls available in the base workspace. The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

### Settings

**Default:** Variant

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression.

### Command-Line Information

To programmatically change this parameter, access the `VariantControl` parameter of the child subsystem or model inside the parent variant subsystem. For example, consider a Variant Subsystem block `LeftController` that contains two variant choices: `Linear` and `Nonlinear`. To edit the variant control for `Linear`, run the following command:

```
set_param('rtwdemo_preprocessor_subsys/LeftController/Linear', ...
'VariantControl', 'NONLINEAR');
```

**Structure field:** Represented by the read-only `variant.Name` field in the `Variant` parameter structure

**Type:** character vector

**Value:** Variant control that is associated with the variant choice.

**Default:** ''

## Condition (read-only)

Displays the **Condition** for the variant controls that are of type `Simulink.Variant` object.

### Settings

A read-only field, based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

### See Also

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

Controlengineers.ir

## Override variant conditions and use following variant

Specify whether to designate the active variant from the evaluation of the variant conditions or from the value of the **Variant** parameter.

For **Override variant conditions and use following variant** option, the variant control need not be a boolean condition expression, or a `Simulink.Variant` object. Variant controls that start with a % symbol are ignored.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Off

On

Override the variant conditions and set the active variant to the variant choice represented by the **Variant** field.

Off

Determine the active variant by the value of the variant conditions.

### Dependencies

This parameter enables **Variant**.

### Command-Line Information

**Parameter:** `OverrideUsingVariant`

**Type:** character vector

**Value:** '' if no overriding variant is specified.

**Default:** ''

### See Also

- “Working with Variant Choices”

## Variant

Specify the name of the variant to use if you select **Override variant conditions and use the following variant**.

### Settings

**Default:** ''

Must be a valid MATLAB identifier.

### Tips

You can use the **Variant** drop-down list to see a list of all variants currently in the base workspace.

### Dependencies

**Enable variants** and **Override variant conditions and use the following variant** enables this parameter.

### Command-Line Information

**Parameter:** OverrideUsingVariant

**Type:** character vector

**Value:** Specified by the variant control expression.

### See Also

- Simulink.Variant

## Analyze all choices during update diagram and generate preprocessor conditionals

When generating code for an ERT target, this parameter determines whether variant choices are enclosed within C preprocessor conditional statements (`#if`).

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Dependencies

- The check box is available for generating only ERT targets.
- **Override variant conditions and use following variant** is cleared ('off')

### Command-Line Information

**Parameter:** GeneratePreprocessorConditionals

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

- “Define, Configure, and Activate Variants”
- “Variant Systems” (Embedded Coder)

## Propagate conditions outside of variant subsystem

When you select this option, Simulink propagates the variant conditions outside of the Variant Subsystem block to determine which components of the model are active during simulation.

When you select this option, the variant badge indicates the change.

### Settings

**Default:** Disabled

### Command-Line Information

**Parameter:** PropagateVariantConditions

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

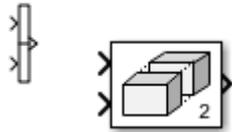

### Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

**Introduced in R2010b**

## Vector Concatenate, Matrix Concatenate

Concatenate input signals of same data type to create contiguous output signal

### Library

Math Operations, Signal Routing

### Description

The Concatenate block concatenates the signals at its inputs to create an output signal whose elements reside in contiguous locations in memory.

---

**Tip:** The Concatenate block is useful for creating an output signal that is nonvirtual. However, to create a vector of function calls, use a Mux block instead.

---

You use a Concatenate block to define an array of buses. For details about defining an array of buses, see “Combine Buses into an Array of Buses”.

The Concatenate block operates in either vector or multidimensional array concatenation mode, depending on the setting of its **Mode** parameter. In either case, the block concatenates the inputs from the top to bottom, or left to right, input ports.

### Vector Mode

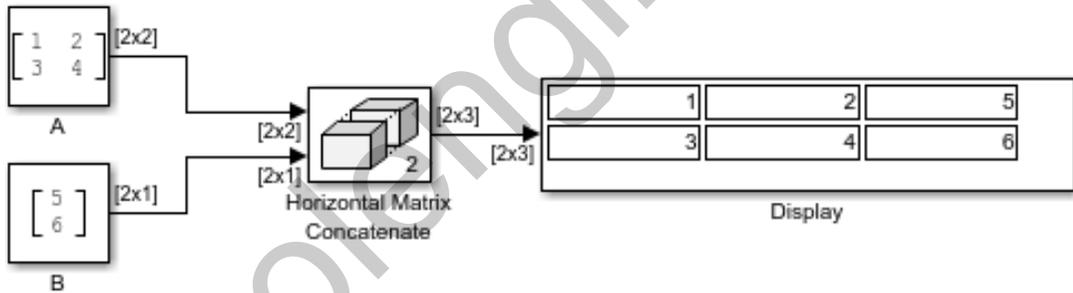

In vector mode, all input signals must be either vectors or row vectors [1xM matrices] or column vectors [Mx1 matrices] or a combination of vectors and either row or column vectors. The output is a vector if all inputs are vectors.

The output is a row or column vector if any of the inputs are row or column vectors, respectively.

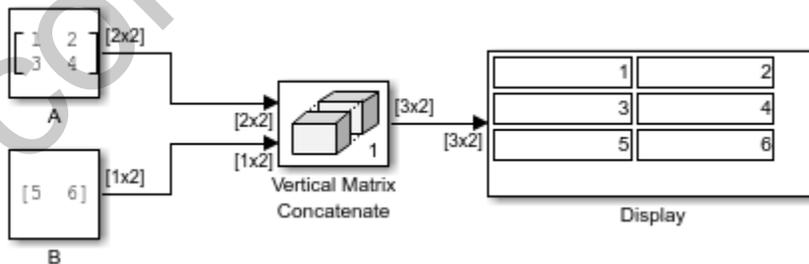

## Multidimensional Array Mode

Multidimensional array mode accepts vectors and arrays of any size. It assumes that the trailing dimensions are all ones for input signals with lower dimensionality. For example, if the output is 4-D and the input is  $[2 \times 3]$  (2-D) this block treats the input as  $[2 \times 3 \times 1 \times 1]$ . The output is always an array. The block's **Concatenate dimension** parameter allows you to specify the output dimension along which the block concatenates its input arrays.

If you set the **Concatenate dimension** parameter to 2 and inputs are 2-D matrices, the block performs horizontal matrix concatenation and places the input matrices side-by-side to create the output matrix, for example:

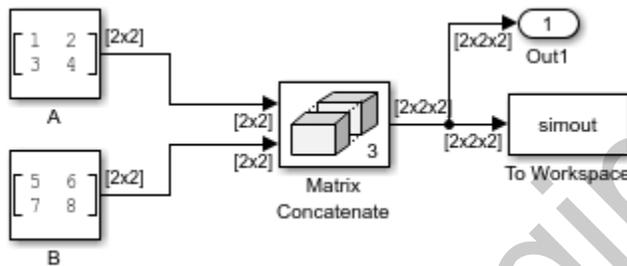

If you set the **Concatenate dimension** parameter to 1 and inputs are 2-D matrices, the block performs vertical matrix concatenation and stacks the input matrices on top of each other to create the output matrix, for example:

For horizontal concatenation, the input matrices must have the same column dimension. For vertical concatenation, the input matrices must have the same row dimension. All input signals must have the same dimension for all dimensions other than the concatenation dimensions.

If you set the **Mode** parameter to **Multidimensional array**, the **Concatenate dimension** parameter to **3**, and the inputs are 2-D matrices, the block performs multidimensional matrix concatenation, for example:

## Data Type Support

Accepts signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. All inputs must be of the same data type. Outputs have the same data type as the input.

For more information, see “Data Types Supported by Simulink”.

## Parameters

### Number of inputs

Specifies the number of inputs for the block.

### Settings

Default: 2

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Mode

Select the type of concatenation that this block performs.

### Settings

**Default:** **Vector** (for the Vector Concatenate block), **Multidimensional array** (for the Matrix Concatenate block)

#### Vector

Perform vector concatenation (see “Vector Mode” on page 1-2066 for details).

#### Multidimensional array

Perform matrix concatenation (see “Multidimensional Array Mode” on page 1-2067 for details).

### Dependency

This parameter enables **Concatenate dimension**.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Concatenate dimension

Specifies the output dimension along which to concatenate the input arrays.

### Settings

**Default:** 2

- Enter 1 to concatenate input arrays vertically.
- Enter 2 to concatenate input arrays horizontally.
- Enter a higher dimension to perform multidimensional concatenation on the inputs.

### Dependency

Selecting `Multidimensional` array for **Mode** enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

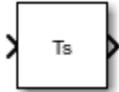

## See Also

cat

Introduced in R2009b

# Weighted Sample Time

Support calculations involving sample time

## Library

Signal Attributes

## Description

The Weighted Sample Time block is an implementation of the Weighted Sample Time Math block. See Weighted Sample Time Math for more information.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point

Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

# Waveform Generator

Output waveforms using signal notations

## Library

Sources

## Description

The Waveform Generator block outputs waveforms based on signal notations that you enter in the **Waveform Definition** table.

This block supports these syntaxes for the signal notations:

- Function syntax — Specify all arguments in the specific order for the signal syntax (see “Supported Waveforms” on page 1-2074).
- Name-value syntax — Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**. For more information, see “Supported Waveforms” on page 1-2074.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

## Supported Operators

Operation	Operator
Absolute value	abs ( )
Addition	+
Division	/

Operation	Operator
Multiplication	*
Parentheses	( )
Subtraction	-
Unary minus	-

The Waveform block observes the following rules of operator precedence:

- 1 ( )
- 2 + - (unary)
- 3 \* /
- 4 + -

## Supported Waveforms

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. To add a waveform definition, click **Add**. The new waveform appears as an empty character vector. The block interprets empty character vectors or white space character vectors as ground.

To remove a waveform definition, click **Remove**. You can select multiple waveforms using **Ctrl+click** or **Shift+click**.

- “Constant” on page 1-2074
- “Gaussian Noise” on page 1-2075
- “Pulse” on page 1-2076
- “Sawtooth” on page 1-2077
- “Sine Wave” on page 1-2078
- “Square” on page 1-2080
- “Step” on page 1-2081

### Constant

Constant values can be:

- Numbers
- Workspace variables
  - Scalar, real variables only
- Built-in MATLAB constant, pi

### Examples

- 1
- 1.1
- x
- pi

## Gaussian Noise

### Syntax

```
gaussian(mean,variance,seed)
```

```
gaussian('Mean',mean,'Variance',variance,'Seed',seed)
```

### Input Arguments

- **mean** — Mean value of the random variable output.
  - Default: 0
- **variance** — Standard deviation squared of the random variable output.
  - Default: 1
  - Value: Positive constant or positive real scalar variable
- **seed** — Initial seed value for the random number generator.
  - Default: 0
  - Value: Constant or real scalar variable

### Example

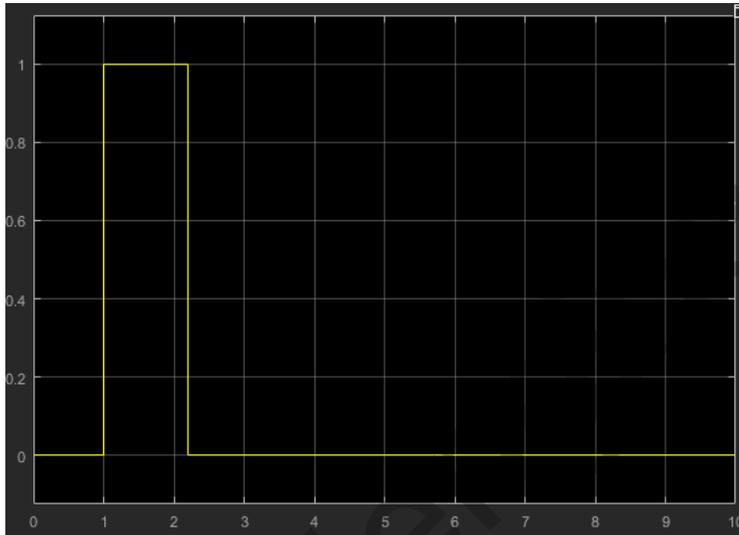

```
gaussian('Mean',0,'Variance',10,'Seed',1)
```

- Value: Positive constant or positive real scalar variable

### Example

```
pulse('Amplitude',1,'TriggerTime',1,'Duration',1)
```

## Sawtooth

### Syntax

```
sawtooth(amplitude,frequency,phase_offset)
```

```
sawtooth('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)
```

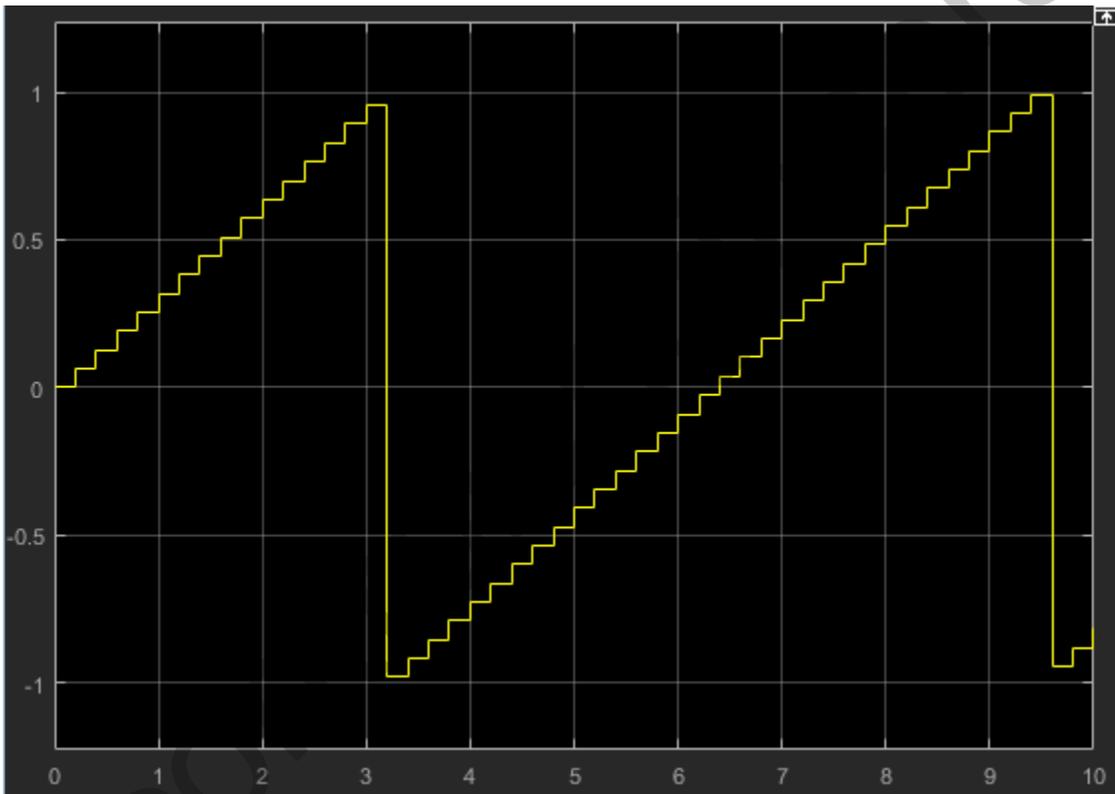

### Input Arguments

- **amplitude** — Sawtooth peak value.
  - Default: 1
- **frequency** — Waveform frequency, in rad/s.
  - Default: 1

- `phase_offset` — Horizontal signal shift, based on elapsed simulation time, in seconds.
  - Default: 0

**Example**

`sawtooth('Amplitude',1,'Frequency',1,'Phase',0)`

**Sine Wave**

**Syntax**

`sin(amplitude,frequency,phase_offset)`

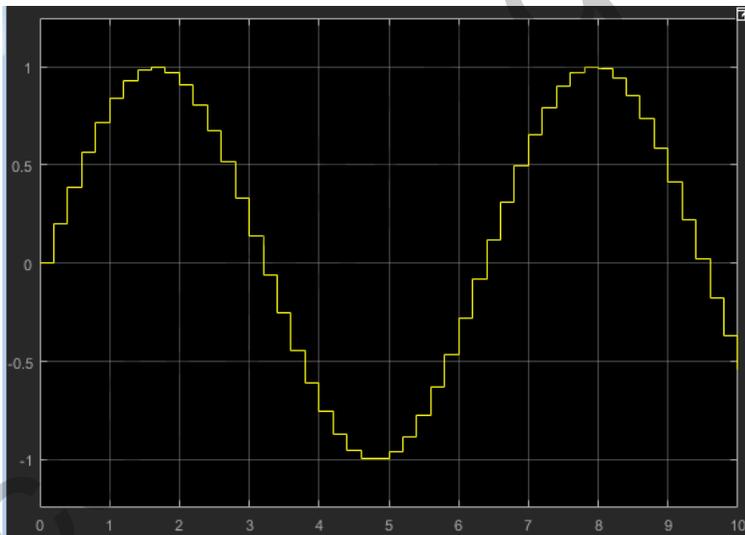

`sin('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)`

### Input Arguments

- `amplitude` — Amplitude of sine wave.
  - Default: 1
- `frequency` — Waveform frequency, in rad/s.
  - Default: 1
- `phase_offset` — Phase offset, in rads.
  - Default: 0

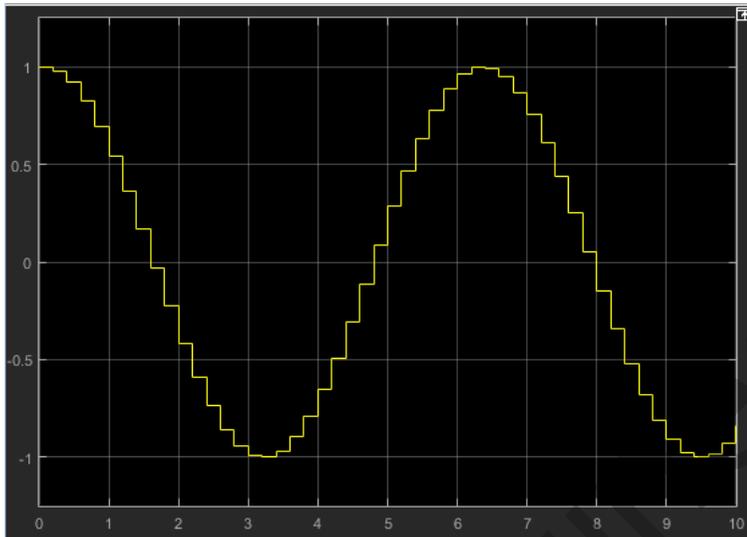

### Examples

`sin('Amplitude',1,'Frequency',1,'Phase',0)`

To get the cosine waveform:

`sin('Amplitude',1,'Frequency',1,'Phase',pi/2)`

## Square

### Syntax

```
square(amplitude,frequency,phase_delay,duty_cycle)
```

```
square('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_delay,...  
'DutyCycle',duty_cycle)
```

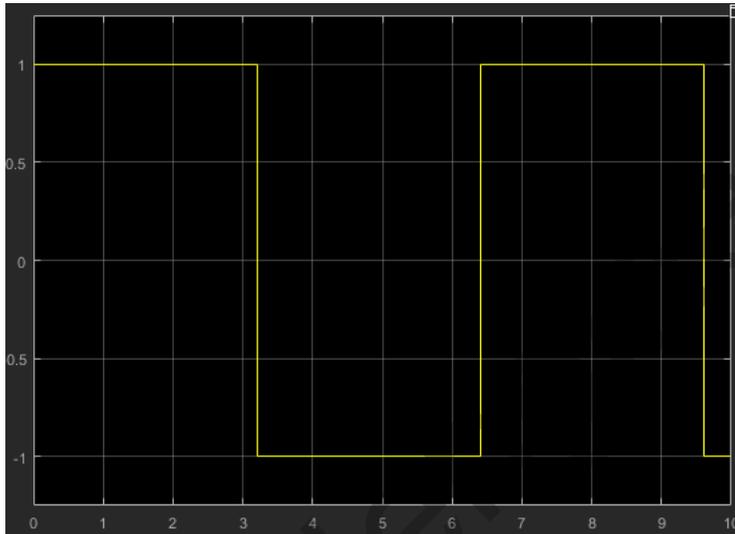

### Input Arguments

- **amplitude** — Amplitude of signal.
  - Default: 1
- **frequency** — Waveform frequency in rad/s.
  - Default: 1
- **phase\_delay** — Horizontal signal shift based on elapsed simulation time, in seconds.
  - Default: 0
- **duty\_cycle** — Percentage of high signal per period (0–100%). The block clips the minimum signal to 0% and the maximum signal to 100%.

- Default: 50

### Example

```
square('Amplitude',1,'Frequency',1,'Phase',0,'DutyCycle',50)
```

### Step

#### Syntax

```
step(step_time,initial_value,final_value)
```

```
step('StepTime',step_time,'InitialValue',initial_value,'FinalValue',final_value)
```

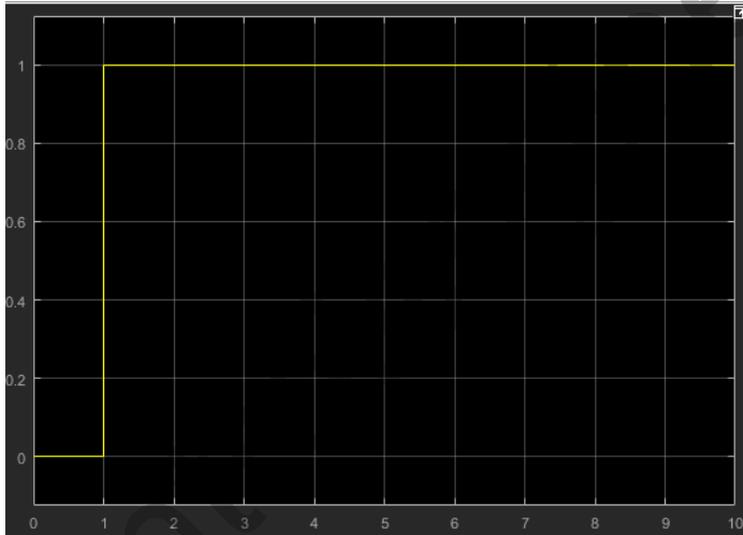

#### Input Arguments

- **step\_time** — Elapsed simulation time when signal changes from **initial value** to **final value**, in seconds.
  - Default: 1
  - Value: Constant or positive real scalar variable.

- `initial_value` — Value of signal when elapsed simulation time is less than `step_time`, in seconds.
  - Default: 0
- `final_value` — Value of signal when elapsed simulation time is greater than or equal to step time, in seconds.
  - Default: 1

### Example

```
step('StepTime',1,'InitialValue',0,'FinalValue',1)
```

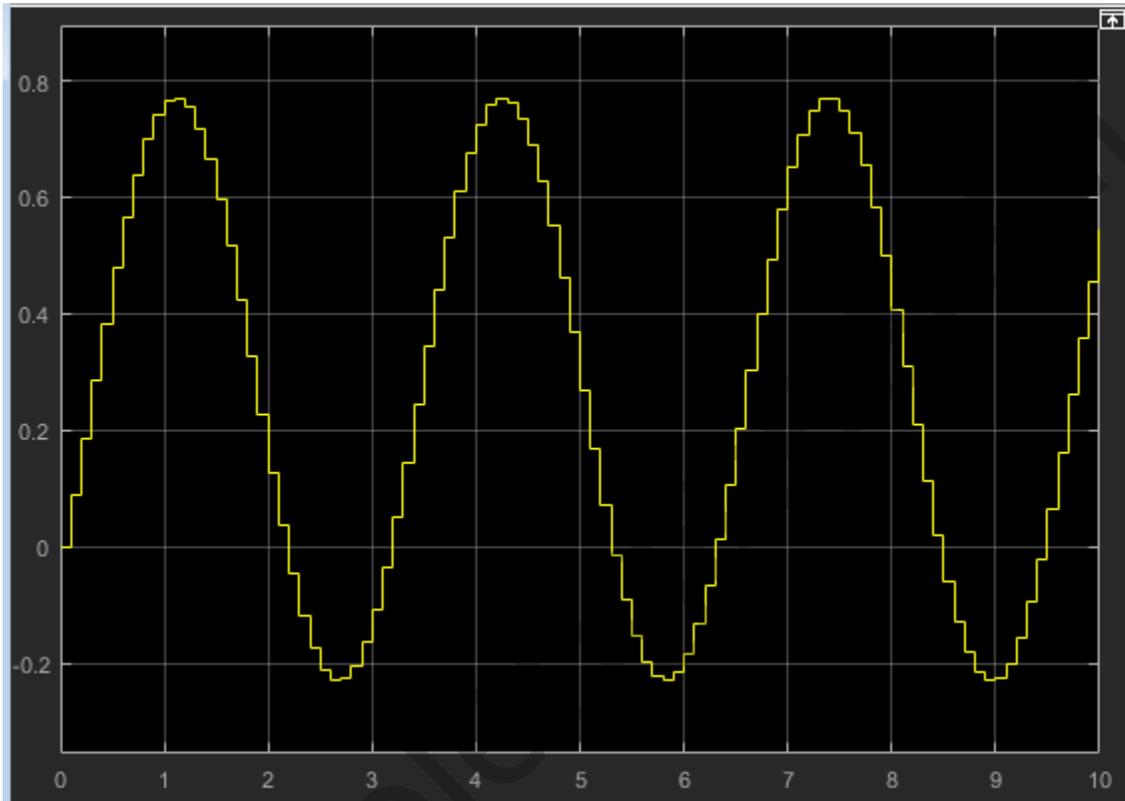

## Supported Operations

The Waveform Generator block outputs one signal at a time. You can change this output signal. Express frequency and phase offset parameters in radians. You can also:

- Nest signal notations, for example:

```
sin('Amplitude',sin('Amplitude',1,'Frequency',1,'Phase',0),'Frequency',1,'Phase',1)
```

- Reference real scalar variables in the base or model workspace, for example:

`sin('Amplitude',x,'Frequency',y,'Phase',z)`

$x$ ,  $y$ , and  $z$  exist in the base workspace.

For more information on waveforms, see “Supported Waveforms” on page 1-2074.

To quickly determine the response of a system to different types of inputs, you can vary the output signal of the Waveform Generator block while a simulation is in progress.

## Data Type Support

The Waveform Generator block outputs scalar values. The default data type is double. However, the block also supports a large subset of Simulink data types, including fixed point (see “Output data type” on page 1-748).

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Output Signal

Select the signal. The number corresponds to the line item in the **Waveform Definition** table. You can change this parameter while a simulation is running.

#### Settings

Default: 1

#### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

## Waveform Definition

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. For more information on waveform definitions and how to enter them, see “Supported Waveforms” on page 1-2074.

### Settings

Default: none

Controlengineers.ir

## Output minimum

Lower value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

### Command-Line Information

**Parameter:** OutMin

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output maximum

Upper value of the output range that Simulink checks.

### Settings

**Default:** [ ] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”)
- Automatic scaling of fixed-point data types
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

---

**Note:** **Output maximum** does not saturate or clip the actual output signal. Use the **Saturation** block instead.

---

### Command-Line Information

**Parameter:** OutMax

**Type:** character vector

**Value:** '[ ]'

**Default:** '[ ]'

## Output data type

Specify the output data type.

### Settings

**Default:** Inherit: Inherit via back propagation

**Inherit:** Inherit via back propagation

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a **Data Type Propagation** block. Examples of how to use this block are available in the Signal Attributes library **Data Type Propagation Examples** block.

**Inherit:** Inherit via back propagation

Use data type of the driving block.

**double**

Output data type is **double**.

**single**

Output data type is **single**.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`boolean`

Output data type is `boolean`.

`fixdt(1,16)`

Output data type is fixed point `fixdt(1,16)`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

### **Command-Line Information**

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### **See Also**

See “Control Signal Data Types” for more information.

## Data type override

Specify data type override mode for this signal.

### Settings

**Default:** double

#### Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

#### Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

### Tip

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Dependency

This parameter appears only when the **Mode** is **Built in** or **Fixed point**.

## Signedness

Specify whether you want the fixed-point data as signed or unsigned.

### Settings

**Default:** Signed

#### Signed

Specify the fixed-point data as signed.

#### Unsigned

Specify the fixed-point data as unsigned.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Word length

Specify the bit size of the word that holds the quantized integer.

### Settings

**Default:** 16

**Minimum:** 0

**Maximum:** 32

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

### Settings

**Default:** Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

### Dependencies

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**
- **Bias**

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specifying a Fixed-Point Data Type”.

## Fraction length

Specify fraction length for fixed-point data type.

### Settings

**Default:** 0

Binary points can be positive or negative integers.

### Dependencies

Selecting **Scaling** > **Binary point** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

Controlengineers.ir

## Slope

Specify slope for the fixed-point data type.

### Settings

**Default:**  $2^0$

Specify any positive real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Bias

Specify bias for the fixed-point data type.

### Settings

**Default:** 0

Specify any real number.

### Dependencies

Selecting **Scaling** > **Slope** and **bias** enables this parameter.

### See Also

For more information, see “Specifying a Fixed-Point Data Type”.

## Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

### Settings

**Default:** Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

### Command-Line Information

**Parameter:** LockScale

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

### See Also

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

## Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Settings

**Default:** Floor

#### Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

#### Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

#### Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

#### Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

#### Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

#### Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

#### Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

### Command-Line Information

**Parameter:** RndMeth

**Type:** character vector

**Value:** 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

**Default:** 'Floor'

### See Also

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

controlengineers.ir

## Saturate on integer overflow

Specify whether overflows saturate.

### Settings

**Default:** Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

### Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Command-Line Information

**Parameter:** SaturateOnIntegerOverflow

**Type:** character vector

**Value:** 'off' | 'on'

**Default:** 'off'

## Sample time

Enter the time interval between sample time hits or specify -1 to inherit the sample time.

### Settings

Default: 0.1

This value cannot be 0 (continuous) or inf (constant). For more information, see “Sample Time”.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

Controlengineers.ir

## Mode

Select the category of data to specify.

### Settings

**Default:** Inherit

#### Inherit

Inheritance rules for data types. Selecting **Inherit** enables **Inherit** via back propagation.

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

### Dependency

Clicking the **Show data type assistant** button enables this parameter.

### Command-Line Information

See “Block-Specific Parameters” on page 6-105 for the command-line information.

### See Also

See “Specify Data Types Using Data Type Assistant”.

controlengineers.ir

## >> (Show data type assistant)

# Weighted Sample Time Math

Support calculations involving sample time

## Library

Math Operations

## Description

The Weighted Sample Time Math block adds, subtracts, multiplies, or divides its input signal,  $u$ , by a weighted sample time,  $T_s$ . If the input signal is continuous,  $T_s$  is the sample time of the Simulink model. Otherwise,  $T_s$  is the sample time of the discrete input signal. If the input signal is constant, Simulink assigns a finite sample time to the block based on its connectivity and context.

You specify the math operation with the **Operation** parameter. Additionally, you can specify to use only the weight with either the sample time or its inverse.

Enter the weighting factor in the **Weight value** parameter. If the weight,  $w$ , is 1, that value does not appear in the equation on the block icon.

The block computes its output using the precedence rules for MATLAB operators (see “Operator Precedence” (MATLAB) in the MATLAB documentation). For example, if the **Operation** parameter specifies  $+$ , the block calculates output using this equation:

$$u + (T_s * w)$$

However, if the **Operation** parameter specifies  $/$ , the block calculates output using this equation:

$$(u / T_s) / w$$

## Data Type Support

The Weighted Sample Time Math block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Operation

Specify operation to use: +, -, \*, /, Ts Only, or 1/Ts Only.

### Weight value

Enter the weight of sample time.

### Implement using

Select one of two modes: online calculations or offline scaling adjustment. This parameter is visible only when you set **Operation** to \* or /.

Result of (Ts * w)	Output Data Type of Two Modes	Block Execution
A power of 2, or an integer value	The same, when <b>Output data type</b> is Inherit: Inherit via internal rule	Equally efficient in both modes
Not power of 2 and not an integer value	Different	More efficient for the offline scaling mode

**Note:** When the **Implement using** parameter is not visible, operations default to online calculations.

**Tip:** The **Saturate on integer overflow** parameter is visible only if:

- The **Operation** parameter specifies + or -.

- The **Operation** parameter specifies \* or / and the **Implement using** parameter specifies Online Calculations.

### Output data type

Specify whether the block inherits the output data type by an internal rule or back propagation.

**Tip:** If you enter an expression in the edit field, the expression must evaluate to one of the two inherit rules.

### Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

### Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
	You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.		Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	For all math operations except Ts and 1/Ts
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## While Iterator

Repeatedly execute contents of subsystem at current time step while condition is satisfied

```
> cond while {
> IC    ...
>      }
```

## Library

Ports & Subsystems

## Description

The While Iterator block, when placed in a subsystem, repeatedly executes the contents of the subsystem at the current time step while a specified condition is true.

---

**Note:** Placing a While Iterator block in a subsystem makes it an atomic subsystem if it is not already an atomic subsystem.

---

The output of a While Iterator subsystem cannot be a function-call signal. Otherwise, Simulink displays an error when you simulate the model or update the diagram.

You can use this block to implement the block-diagram equivalent of a C program `while` or `do-while` loop. In particular, use **While loop type** to select one of the following while loop modes:

- do-while

In this mode, the While Iterator block has one input, the while condition input, whose source must reside in the subsystem. At each time step, the block runs all the blocks in the subsystem once and then checks whether the while condition input is true.

If the input is true, the iterator block runs the blocks in the subsystem again. This process continues as long as the while condition input is true and the number of iterations is less than or equal to the **Maximum number of iterations**.

- while

In this mode, the iterator block has two inputs: a while condition input and an initial condition (IC) input. The source of the initial condition signal must be external to the while subsystem. At the beginning of the time step, if the IC input is true, the iterator block executes the contents of the subsystem and then checks the while condition input. If the while condition input is true, the iterator executes the subsystem again. This process continues as long as the while condition input is true and the number of iterations is less than or equal to the **Maximum number of iterations**. If the IC input is false at the beginning of a time step, the iterator does not execute the contents of the subsystem during the time step.

---

**Tip:** Specify a maximum number of iterations to avoid infinite loops, which you can break only by terminating MATLAB.

---

## Data Type Support

Acceptable data inputs for the condition ports are any numeric data type that Simulink supports, as well as any fixed-point type that includes a 0 value. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

The optional output port can output any of the following data types: double, int32, int16, or int8.

## Parameters

### Maximum number of iterations

Specify the maximum number of iterations allowed. A value of -1 allows any number of iterations as long as the while condition input is true. Note that if you specify -1 and the while condition never becomes false, the simulation will run forever. In this case, the only way to stop the simulation is to terminate the MATLAB process. Therefore, do not specify -1 as the value of this parameter unless you are certain that the while condition becomes false at some point in the simulation.

## While loop type

Specify the type of while loop that this block implements.

## States when starting

Set this field to **reset** if you want the iterator block to reset the states of the blocks in the while subsystem to their initial values at the beginning of each time step (i.e., before executing the first loop iteration in the current time step). To cause the states of blocks in the subsystem to persist across time steps, set this field to **held** (the default).

## Show iteration number port

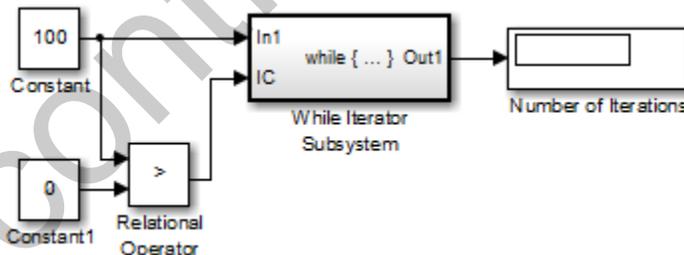

If you select this check box, the While Iterator block outputs its iteration value. This value starts at 1 and is incremented by 1 for each succeeding iteration. By default, this check box is not selected.

## Output data type

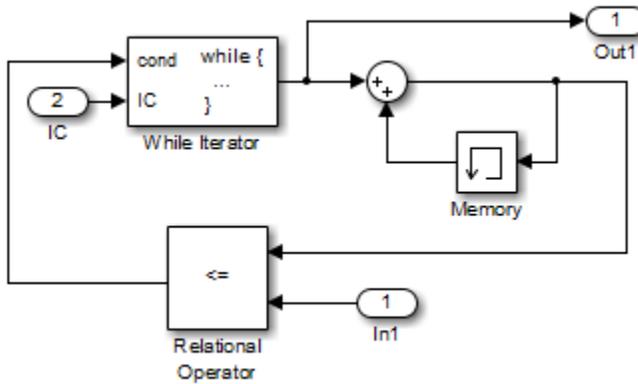

If you select the **Show iteration number port** check box (the default), this field is enabled. Use it to set the data type of the iteration number output to **int32**, **int16**, **int8**, or **double**.

## Examples

The While Iterator block can optionally output the current iteration number, starting at 1. The following model uses this capability to compute N, where N is the first N integers whose sum is less than 100.

The contents of the While Iterator subsystem are:

The While Iterator block uses the following parameter settings:

- **Maximum number of iterations** set to 20
- **States when starting** set to reset

The model is the diagrammatic equivalent of the following pseudocode:

```

max_sum = 100;
sum = 0;
iteration_number = 0;
cond = (max_sum > 0);
while (cond != 0) {
    iteration_number = iteration_number + 1;
    sum = sum + iteration_number;
    if (sum > max_sum OR iteration_number > max_iterations)
        cond = 0;
}
    
```

## Characteristics

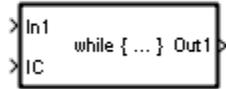

Direct Feedthrough	No
Sample Time	Inherited from the driving block
Scalar Expansion	No
Dimensionalized	No
Zero-Crossing Detection	No

Introduced before R2006a

controlengineers.ir

# While Iterator Subsystem

Represent subsystem that executes repeatedly while condition is satisfied during simulation time step

## Library

Ports & Subsystems

## Description

The While Iterator Subsystem block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem that executes repeatedly while a condition is satisfied during a simulation time step.

See the While Iterator block and “Use Control Flow Logic” for more information.

When using simplified initialization mode, you cannot place any block needing elapsed time within an Iterator Subsystem. In simplified initialization mode, Iterator subsystems do not maintain elapsed time, so Simulink will report an error if any such block (such as the Discrete-Time Integrator block) is placed within the subsystem. For more information on simplified initialization modes, see “Underspecified initialization detection”.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes

Code Generation	Yes
-----------------	-----

Introduced before R2006a

controlengineers.ir

## Width

Output width of input vector

## Library

Signal Attributes

## Description

The Width block generates as output the width of its input vector.

You can use an array of buses as an input signal to a Width block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Data Type Support

The Width block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

The Width block also supports mixed-type signal vectors.

When the **Output data type mode** is not `Choose intrinsic data type`, the block supports only built-in numeric types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

---

**Note** The Width block ignores the **Data type override** setting of the Fixed-Point Tool.

---

### Output data type mode

Specify the output data type to be the same as the input, or inherit the data type by back propagation. You can also choose to specify a built-in data type from the drop-down list in the **Output data type** parameter.

### Output data type

This parameter is visible when you select **Choose intrinsic data type** for **Output data type mode**. Select a built-in data type from the drop-down list.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Constant
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

**Introduced before R2006a**

## Wrap To Zero

Set output to zero if input is above threshold

### Library

Discontinuities

### Description

The Wrap To Zero block sets the output to zero when the input is above the **Threshold** value. However, the block outputs the input when the input is less than or equal to the **Threshold**.

### Data Type Support

The Wrap To Zero block accepts inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The block output has the same data type as the input. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

---

**Tip:** If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to warning or error.

---

## Parameters

### Threshold

When the input exceeds the threshold, the block sets the output to zero.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

## XY Graph

Display X-Y plot of signals using MATLAB figure window

### Library

Sinks

### Description

The XY Graph block displays an X-Y plot of its inputs in a MATLAB figure window.

The block has two scalar inputs. The block plots data in the first input (the  $x$  direction) against data in the second input (the  $y$  direction). (See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.) This block is useful for examining limit cycles and other two-state data. Data outside the specified range does not appear.

A figure window appears for each XY Graph block in the model at the start of simulation.

### Data Type Support

The XY Graph block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

---

**Note:** The XY Graph block does not support stepping back in a simulation.

---

## Parameters

### x-min

Specify the minimum  $x$ -axis value. The default is -1.

### x-max

Specify the maximum  $x$ -axis value. The default is 1.

### y-min

Specify the minimum  $y$ -axis value. The default is -1.

### y-max

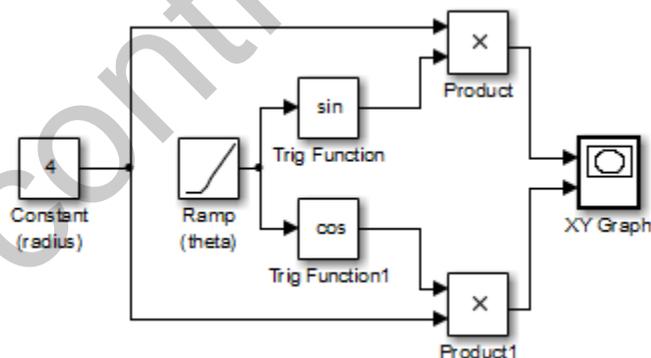

Specify the maximum  $y$ -axis value. The default is 1.

### Sample time

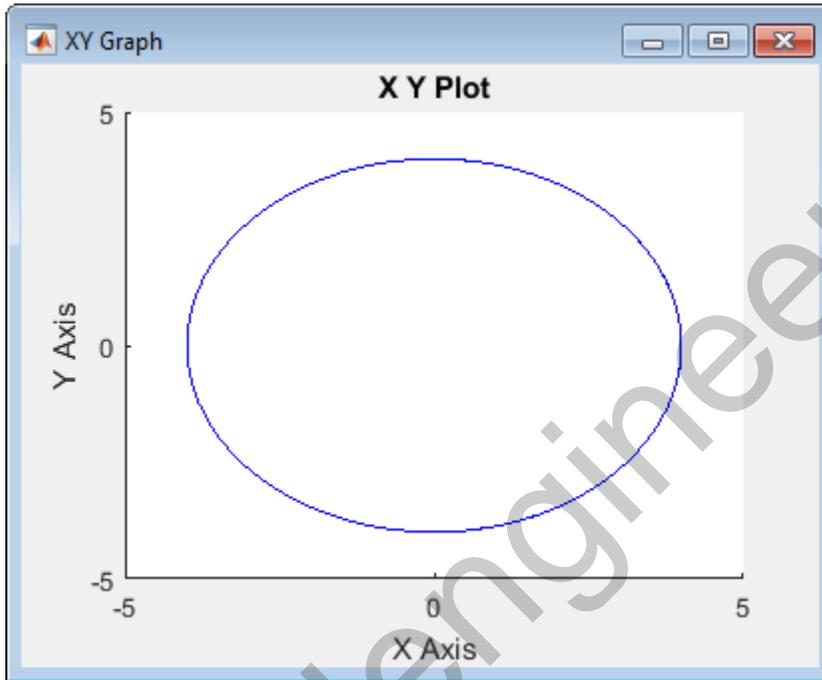

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the Simulink documentation for more information.

## Examples

The following model computes the points that define a circle of radius 4, centered at the origin of the  $x$ - $y$  plane.

When you simulate the model, a figure window appears.

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point
Sample Time	Specified in the <b>Sample time</b> parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	No

**Introduced before R2006a**

# Zero-Order Hold

Implement zero-order hold of one sample period

## Library

Discrete

## Description

The Zero-Order Hold block holds its input for the sample period you specify. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds all elements of the vector for the same sample period.

You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

---

**Tip:** Do not use the Zero-Order Hold block to create a fast-to-slow transition between blocks operating at different sample rates. Instead, use the **Rate Transition** block.

---

## Comparison with Similar Blocks

### Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

## Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_enginewc (Compression subsystem)</li> </ul>
Memory on page 1-1003	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> <li>• sldemo_bounce</li> <li>• sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)</li> </ul>
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> <li>• sldemo_radar_eml</li> <li>• aero_dap3dof</li> </ul>

## Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	Yes	No, because the block can only inherit sample time (from the driving block or the solver used for the entire model).	Yes
Support for frame-based signals	Yes	No	Yes

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Support for state logging	Yes	No	No

## Data Type Support

The Zero-Order Hold block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

## Parameters

### Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the online documentation for more information.

Do not specify a continuous sample time, either 0 or  $[0, 0]$ . This block supports only discrete sample times. When this parameter is -1, the inherited sample time must be discrete and not continuous.

## Bus Support

The Zero-Order Hold block is a bus-capable block. The input can be a virtual or nonvirtual bus signal. No block-specific restrictions exist. All signals in a nonvirtual bus input to a Zero-Order Hold block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” for more information.

You can use an array of buses as an input signal to a Zero-Order Hold block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

## Examples

The following models show how to use the Zero-Order Hold block:

- sldemo\_radar\_em1
- aero\_dap3dof

## Characteristics

Data Types	Double   Single   Boolean   Base Integer   Fixed-Point   Enumerated   Bus
Sample Time	Specified in the <b>Sample time</b> parameter
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

## Zero-Pole

Model system by zero-pole-gain transfer function

$$\frac{(s - 1)}{s(s + 1)}$$

## Library

Continuous

## Description

The Zero-Pole block models a system that you define with the zeros, poles, and gain of a Laplace-domain transfer function. This block can model single-input single output (SISO) and single-input multiple-output (SIMO) systems.

## Conditions for Using This Block

The Zero-Pole block assumes the following conditions:

- The transfer function has the form
